The views expressed in this paper are those of the author(s) and do not necessarily reflect the views or policies of the Asian Development Bank.

The ADB Economics Working Paper Series is a forum for stimulating discussion and eliciting feedback on ongoing and recently completed research and policy studies undertaken by the Asian Development Bank (ADB) staff, consultants, or resource persons. The series deals with key economic and development problems, particularly those facing the Asia and Pacific region; as well as conceptual, analytical, or methodological issues relating to project/program economic analysis, and statistical data and measurement. The series aims to enhance the knowledge on Asia's development and policy challenges; strengthen analytical rigor and quality of ADB's country partnership strategies, and its subregional and country operations; and improve the quality and availability of statistical data and development indicators for monitoring development effectiveness.

The ADB Economics Working Paper Series is a quick-disseminating, informal publication whose titles could subsequently be revised for publication as articles in professional journals or chapters in books. The series is maintained by the Economics and Research Department.

#### Abstract

This paper provides trade flow projections for major Asian developing economies (ADEs) up to 2030 against the backdrop of an in-depth analysis of policy shifts and trade patterns over the past 4 decades. Merchandise trade of ADEs has grown at a much faster rate in the global context, with a distinct intraregional bias. Global production sharing has become a unique feature of the economic landscape of the region, with the People's Republic of China playing a pivotal complementary role as the premier assembly center within the regional production networks. According to the projections made within the standard gravity modelling framework, total real nonoil trade of ADEs would increase at an average annual rate of 8.2 during the next 2 decades, with a notable convergence of individual countries' rates to the regional average. The share of intraregional trade in total nonoil trade would increase steadily from 53\% in 2010 to $58 \%$ in 2030. The trade-to-GDP ratio would increase from 39.4\% and 74.4\% between these 2 years. These predictions need to be treated with caution as they are based on the assumption that the trade structure pertaining to the estimation period will remain unchanged in the next 2 decades.

## I. Asian Trade Flows: Trends, Patterns, and Projections to 2030

The purpose of is paper is two-fold: to examine emerging trends and patterns of merchandise trade in Asia over the past 4 decades and to generate projections for Asian trade through to 2030 using the standard gravity model of international trade. The paper covers 12 major Asian developing economies (ADEs), namely, the People's Republic of China (PRC); Hong Kong, China; India; Indonesia; the Republic of Korea; Malaysia; Pakistan; the Philippines; Singapore; Taipei,China; Thailand; and Viet Nam. ${ }^{1}$ To gain perspective, trends and patterns of merchandise trade of the ADEs are examined in the context of the commercial policy environment, growth and structural change in these countries, and institutional and technological factors governing international production and global trade. Relating to the latter, a key theme running through this paper is the implications of global production sharing ${ }^{2}$-that is, the geographic separation of activities involved in producing a good (or service) across two or more countries-for rapid trade growth in these countries.

The paper is organized as follows. Section II briefly surveys the policy environment shaping countries' participation in the global economy. Section III examines general patterns of trade since 1970, encompassing trade flows over time in aggregate, by major partners, and by major commodity groups. This section also examines geographic patterns of trade, with emphasis on the implications of the growing importance of global production sharing. Section IV presents the estimates of trade equations for the 12 economies and preliminary trade flow predictions based on these estimates. The final section summarizes the main findings and draws out some general inferences.

## II. The Policy Context

Rapid growth and structural change in ADEs over the past 4 decades has been underpinned by notable reduction in barriers to international trade. There has been significant import liberalization in the PRC; Indonesia; the Republic of Korea; Malaysia; the Philippines; Taipei,China; and Thailand since the mid-1980s. India and Viet Nam embarked on trade reforms in the early 1990s. Trade liberalization in all these economies

1 These economies account for over $96 \%$ of total foreign trade of all countries in Northeast and Southeast Asia.
2 An array of alternative terms have been used to describe this phenomenon, including international production fragmentation, vertical specialization, slicing the value chain, and outsourcing.
has been predominantly unilateral and nondiscriminatory, and was also aided by multilateral liberalization under the General Agreement on Tariffs and Trade and its successor, the World Trade Organization (since 1991). Historically countries in Asia have not been enthusiastic toward preferential trading agreements (PTAs), with the exception of some trade preferences within the ASEAN region that presumably had only trivial trade flow effects. Since then, the advent of the European Union and the rise of regionalism in North America led to a proliferation of PTAs in the region. It is too early to assess the trade flow implications of these PTAs, but the available circumstantial evidence suggest that so far the impact would have been rather small. The preference utilization rates of the PTAs remains very low, given the narrow preference margins resulting from the ongoing process of multilateral and unilateral tariff reductions, and the administrative cost and complications involved in meeting the rules of origins involved for benefiting from tariff preferences (Plummer 2007, Baldwin 2006).

This section aims to provide an overview of the process of trade opening in the region and the current state of openness to trade. The discussion is based on three broad sets of indicators of openness to international trade, namely, the Sachs-Warner binary classification, revealed trade orientation measured as exports or total trade (exports + imports) as a percentage of GDP, and average tariff rate. All these measures have their shortcomings (as discussed below), but together they enable us to assert with reasonable confidence whether an economy is broadly open.

Table 1 depicts the patterns and chronology of liberalization status of Asian economies based on the Sachs-Warner binary index of trade regime shifts. The index classifies the postwar trade policy history of a given economy into two subperiods (closed economy $=0$ and open economy $=1$ ) based on the timing of sustained trade opening. ${ }^{3}$ This is of course a somewhat blunt characterization of liberalization status. Given the complexity of economic policy reform, a binary classification of liberalization status naturally involves a significant element of subjectivity (Rodriguez and Rodrik 2000), simply binary ( $0 / 1$ ) classification. However it has the attraction of a clear analytical foundation, a long time series, and comprehensive country coverage.

According to this classification, Hong Kong, China; Malaysia; Singapore; and Thailand have always remained open throughout the postwar era. Japan; the Republic of Korea; and Taipei, China completed the transition from closed to open trade regimes by the 1960s. By the turn of the century (the end point of the time coverage of Wacziarg and Welch 2003), only the PRC and Viet Nam, which are not covered in the classification, remained closed. However, in the ensuing years these two countries have undertaken significant tariff cuts (Table 2) and dismantled most nontrade barriers (NTBs) and restrictions on foreign exchange dealings on current account transactions mainly as

[^3]part of their WTO accession commitments ${ }^{4}$ (Bergesten et al. 2009, Athukorala 2006). Consequently, from about 2005, the "socialist economic system" characterization remains the only Sachs-Warner closed economy criterion applicable to these countries.

Table 1: Liberalization Status/Dates and Data on Trade Policy ${ }^{1}$

|  | Liberalization <br> Status/Dates during ${ }^{1}$ 1945-2000 | Data on Trade Policy (Sachs-Warner criteria) |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Average Tariff ${ }^{2}$ (1990-99) <br> (\%) | NTB Coverage ${ }^{3}$ (1990-98) (\%) | Black-market Premium ${ }^{4}$ (1990-99) (\%) | Export Marketing <br> Boards/Socialist State |
| Hong Kong, China | Always open | - | 2.1 | -0.02 | 0 |
| Malaysia | Always open | 11.7 | 19.6 | 1.35 | 0 |
| Singapore | Always open | 0.32 | 2.1 | 0.8 | 0 |
| Thailand | Always open | 29.54 | 17.5 | 1.8 | 0 |
| Taipei,China | 1963 | 9.85 | - | 0.95 | 0 |
| Korea, Rep. of | 1968 | 11.3 | 25.0 | 0.03 | 0 |
| Indonesia | 1970 | 16.27 | 31.3 | 7.1 | 0 |

| China, People's Rep. of ${ }^{5}$ | Remains closed | 31.06 | - | 35.89 | 1 |

NTB = nontrade barrier.

- means exact figure is not available, but it is commonly believed to be well below the Sachs-Warner criteria.
${ }^{1}$ Based on the application of Sachs-Warner criteria, which classifies a country as open if does not satisfy all these five criteria for the entire duration of a give time period: (i) Nontariff barrier coverage of intermediate and capital goods imports of $40 \%$ or more; (ii) Average tariff on intermediate and capital goods imports of $40 \%$ or more; (iii) A black market exchange rate that is depreciated by $20 \%$ or more relative to the official exchange rate; (iv) A socialist economic system (as defined by Kornai 1992); and (v) A state monopoly on major exports.
2 Unweighted average tariff.
${ }^{3}$ Core nontariff barrier frequency on capital goods and intermediates, including quotas, licensing, prohibitions, and administered pricing.
${ }^{4}$ [(parallel exchange rate/official exchange rate) - 1]*100.
${ }^{5}$ Remains closed, based on the black market exchange rate premium.
Sources: Sachs and Warner 1995 and Wacziarg and Welch (2003).

Average applied most favored nation (MFN) tariff rates of ADEs are summarized in Table 2. It is important to note at the outset that tariff rates can be used to compare trade openness across countries when there is little reliance on NTBs; in the presence of binding NTBs, tariff rates naturally tend to understate the trade-impeding impact of the trade regime. Average tariff comparisons also need to allow for partial reforms. Most countries in the region have been compensating exporters for duties paid on imported inputs. These typically take the form of duty exemptions or drawbacks, or the establishment of export processing zones. However there is evidence that almost all countries in the region have dismantled most binding NTBs and scaled down selective incentives for export producers (Panagariya 2007, Krueger 2010).

Sources: Nicita and Olarreaga (2006) and WTO (2006).

There has been a universal trend toward lower tariffs across the ADEs over the past 2 decades. In some economies, the declines have been very large, more than halving since the 1980s as in the PRC; India; Japan; the Republic of Korea; the Philippines; Taipei,China; and Thailand. Within Asia, the East Asian economies are generally more open than those of South Asia. In 2004, India and Pakistan had the highest average tariffs, with the Indian figure being three times that of the PRC. Hong Kong, China and Singapore have of course always had negligible protection. The average tariff rates in other countries mostly range up to $10 \%$. Importantly, though not adequately recorded here, the East Asian economies were much quicker than the two major South Asian countries to adopt partial reforms that enabled exporters to operate on an effective freetrade footing.

The export/GDP ratio, ${ }^{5}$ the standard revealed openness measure, is reported in Table 3. The trade/GDP ratio is a comparison between a net and a gross concept; trade is measured in gross terms (intermediate material inputs + value added) whereas GDP is essentially measured on a value-added basis (that is, net of intermediate material inputs). Thus, the measured change in trade orientation is sensitive to changes in import intensity of export production. As will be seen later, over the past decade there has been a palpable shift in the export composition away from primary products and toward laborintensive light manufacturing and, more recently, the ongoing process of international production fragmentation within high-tech industries. The increase in measured trade orientation could partly reflect the fact that these new product lines are relatively

[^5]more import-intensive compared to the former. Another limitation for cross-country comparisons is that the ratios need to be adjusted for size, in recognition of the fact that small countries by definition will trade more than larger ones. However, as already noted, the usefulness of this measure in its own right as an indicator of trade openness is limited because, by construct, it is driven by structural shifts in production and trade patterns. Of particular relevance in this connection is the ongoing process of international production fragmentation, which involves small value-added additions at various stages of the production process of a given final good in various countries, thus resulting in inflated trade values relative to GDP. Even in small countries, at least 60\% of GDP is generated by nontradable sectors. Thus an export share of much more than $30 \%-40 \%$ can arise only when export production involves adding fairly small amounts of value to imported inputs (Krugman 1995, 335). These limitations notwithstanding, the intercountry differences and the time profile revealed by this measure are broadly consistent with those already observed.

Openness to trade is a necessary but not sufficient condition for successful global economic integration. Equally important is the conduciveness of the business environment. International competitiveness requires high quality infrastructure, both hard and soft, especially for successful participation in time-sensitive global production and purchasing networks. Labor markets need to reflect underlying supply and demand conditions, with wage growth and differentials driven by productivity. Prudent macroeconomic management is required to provide a stable and predictable commercial policy environment, and to ensure that exchange rate outcomes do not impair competitiveness. Above all, political stability and policy certainty figure prominently among prerequisites for profitable long-term investment, particularly for multinational enterprises (MNEs).

In recent years there have been various attempts to build databases on the business environment of a large number of countries based on investor surveys or other subjective assessments covering large number of countries. Tables 4 and 5 show the rankings of ADEs in two of these that have by far the widest country coverage among the alternative databases, namely, the Doingbusiness database and Logistic Performance Index (LPI) database of the World Bank. Doingbusiness ranks countries ( 85 countries in the latest update) in terms of ease of doing business using 10 criteria. The LPI specifically focuses on the quality of trade-related logistic provisions, based on a worldwide survey of global freight forwarders and express carriers, complemented by a number of qualitative and quantitative indicators of the domestic logistics environment, institutions, and performance of supply chains.

The ease of doing business data summarized in Table 4 confirm the superiority of East Asia over South Asia, with the four Asian newly industrialized economies (NIEs)—Hong Kong, China; the Republic of Korea; Singapore; and Taipei,China—along with Malaysia and Thailand ranking the highest. The PRC ranks ahead of India by a wide margin. The differences between Northeast and Southeast Asia are not significant. Nevertheless this ranking exercise is at best indicative and also presumably reflects the development paradigms of the institution preparing the data. The PRC and Viet Nam fare poorly, in spite of the sweeping reforms of the past 2 decades, and even when they are obviously commercially attractive to foreign investors. Naturally the country ranking in terms of the LPI (Table 5) is remarkably similar to that based on the Doingbusiness database. Singapore tops the overall logistics quality raking. The other major transshipment hub in the region, Hong Kong, China, is fourth on the global ranking and second among ADEs. The data also reveal significant differences among countries at similar levels of development. Countries in Northeast and Southeast Asia have higher rankings. Other East Asian contraries, including the PRC, also compare very favorably compared to developing countries in other parts of the world.
Table 4: Indicators of Ease of Doing Business Ranking of Selected Asian Developing Economies, 2009

## III. Trade Patterns

Rapid trade expansion has been the hallmark of Asia's rise in the global economy. The combined share of ADEs in total world merchandise exports increased continuously from less than $5 \%$ in 1970 to $22 \%$ by 2008 (Figure 1a). ${ }^{6}$ The region accounted for over a third of total increment in world exports over this period. Focusing on world nonoil trade (trade net of oil and gas) to gain a better comparative picture, ${ }^{7}$ the increase in ADEs' world export share turns out to be even sharper, from about 4\% in the early 1970s to over nearly $25 \%$ in 2008 (Figure 1b).

The rise of the PRC has been a dominant factor behind the share increase in the ADEs' world market shares from about the early 1990s. But the upward trend in world market shares of the other countries that began in the early 1970s has continued unabated throughout the period. Thus, on first inspection, there is no indication of the PRC "crowding out" its neighbors-the PRC's market share gains has been at the expense of that of the rest of the world, not from the rest of Asia. This observation is consistent with the inferences coming from a number of recent studies that have systematically examined the impact of the PRC's rise in export performance on the other countries in the region (Athukorala 2009, Greenaway at al. 2008, Eichengreen et al. 2007).

At the individual country level, market share gains have varied notably over time (Table 1). ${ }^{8}$ Among the nine largest ADEs, only Hong Kong, China; Indonesia; and the Philippines have smaller world trade shares than India, which is by far the dominant South Asian economy. Notwithstanding the notable export expansion in recent years, India still accounts for a mere 1.1\% of total world trade, equivalent to less than 5\% of ADEs' total trade. Pakistan is the only country among the 12 ADEs to record a decline in market share (other than Hong Kong, China, whose export production base has "migrated" to the PRC since about the early 1990s).

Rapid export growth in developing Asia has been underpinned by a pronounced shift in export structure away from primary commodities and toward manufactures (Table 6). From about the early 1990s, manufactures accounted for over four fifths of total merchandise exports from these economies, up from 84.3\% in 1969/1970 some 4 decades ago. Given the nature of their resource endowments, the four Asian NIEs (Hong Kong, China; the Republic of Korea; Singapore; Taipei,China) relied very heavily on manufacturing for export expansion from the outset. However, beginning in the 1970s, a notable shift toward manufacturing is observable across all economies, at varying speeds and intensity. The combined shares of the ASEAN countries other than Singapore increased from a mere $11 \%$ to $71.0 \%$ between these two time points. Among individual

[^6]countries, Indonesia and Viet Nam had a significantly lower share of manufactures in their exports, reflecting both their comparative advantage and their later adoption of exportoriented industrialization strategies.

Figure 1a: Share in Total World Merchandise Trade:
Asian Developing Economies and the PRC, 1970-2008 (percent)

Figure 1b: Share in World Nonoil Trade: Asian Developing Economies and the PRC, 1970-2008 (percent)

[^8]Within manufacturing, machinery and transport equipment (SITC 7) played a pivotal role in the structural shift in the export composition of ADEs (Tables 7 and 8). The share of machinery and transport equipment in the export structures of some of the more industrialized economies of East Asia is particularly high. By contrast, that for Indonesia, Viet Nam, and all of South Asia is much smaller. Within the machinery and transport equipment category, information and communication techology (ICT) products have been the most dynamic component of Asian export expansion. By 2007/2008, over 58\% of total world ICT exports originated from Asia, up from $30.8 \%$ in 1994/1995 (Table 8); the PRC accounted for $25.4 \%$ of total world ICT exports, up from $4.2 \%$ in 1994/1995. In electrical goods, the PRC's world market share increased from $3.1 \%$ to $20.6 \%$ between these 2 years.

Asia's share in the other main product categories has also increased over time, though at a slower rate. Of particular interest here is the notable increase in the region's share in miscellaneous manufacturing. This mostly consists of standardized labor-intensive manufactured goods, in particular clothing and footwear. The PRC has accounted for much of this increase but, in contrast to ICT exports, the geographic participation has been broader. Indonesia, India, and Viet Nam (and also a number of low-wage countries in Southeast and South Asia, including Bangladesh, Cambodia, India, Indonesia, Sri Lanka, and Viet Nam not covered in the table) have all recorded impressive gains in market share.

## A. Global Production Sharing

The fast growth of machinery trade in Asia has been driven by rapid growth of international fragmentation of production in world trade and the increasingly deep integration of East Asian countries into the global production networks (Athukorala 2005, Ng and Yeats 2003). Linking Southeast Asia to the global electronics production networks began in 1968 with the arrival of two US companies, National Semiconductors and Texas Instruments, which set up plants in Singapore to assemble semiconductor devices (Athukorala 2008). From about the late 1970s, the MNEs with production facilities in Singapore began to relocate some low-end assembly activities in neighboring countries (particularly in Malaysia, the Philippines, and Thailand) in response to the rapid growth of wages and land prices. Many newcomer MNEs to the region also set up production bases in these countries, bypassing Singapore. From about the early 1990s the emergence of the PRC as the global factory of electrical and electrical goods assembly based on parts and components imported from other countries contributed to rapid expansion of production networks in the region. More recently, regional production networks have begun to expand to Viet Nam. Over the past 3 decades, the process of global production sharing has created a new division of labor among countries in the region, based on skill differences involved in different stages of the production process and relative wages, and improved communication and transport infrastructure (Ando and Kimura 2010). As will be seen below, the formation of production networks has dramatically transformed the spatial patterns of international trade in the region, with a notable "magnification" effect on recorded trade flows operating through multiple border-crossing of parts and components on the expansion of intraregional trade.

The most ubiquitous indicator of the intensity of fragmentation-based specialization in world trade is the share of parts and components in total manufacturing trade (Table 9, Panel A). ${ }^{9}$ Over the past 2 decades there has been a sharp increase in the share of parts and components (henceforth referred to as components for brevity) in world manufacturing trade from $19.3 \%$ in 1992/1993 to $27.1 \%$ in 2006/2007 (Table 9). This share has increased at much faster rate in ADEs, from 17.3\% to 34.0\%. Components share is particularly high among the countries in ASEAN, with all countries in East Asia recording shares well above the world average. The combined component share in manufacturing exports from the ASEAN countries in 2006/2007 amounted to $44.2 \%$, up from $22.7 \%$ in 1992/93. In spite of its intrinsic comparative advantage, India still remains a minor player in this new form of international exchange (Krueger 2010).

In an intercountry comparison, there is a remarkable similarity of component shares in manufacturing exports and imports across all East Asian countries other than the PRC, reflecting overlapping specialization patterns in component assembly and testing among countries in the region. The PRC's manufacturing trade patterns differ from its East Asian neighbors. In particular, the components share in the total manufacturing imports of the PRC (44\% in 2006/2007) is much larger compared to the corresponding share in its manufacturing exports (25.6\%). This difference between the PRC and the other countries in the region is consistent with the earlier observation that the PRC's rise in world trade has brought about a notable shift in the division of labor within regional production networks, with ASEAN countries playing an increasing role in producing parts and components for the rapidly growing final assembly activities in the PRC. The bulk of components used in final assembly in the PRC come from other countries in the region. At the same time, final goods (total exports minus components) account for an overwhelming share of the PRC's exports to the rest of the world, mostly to the EU and the US.

## B. Intraregional Trade

A notable outcome of the rapid expansion of production networks has been been the rapid growth of cross-border trade in parts and components within the regions. For instance, in 2006/2007, components accounted for 53.9\% of intra-ADE exports (59.5\% of imports) compared to $34.0 \%$ in the regions total exports ( $44.2 \%$ of total imports). Interestingly component share in intra-ADE trade is much higher compared to that of intraregional trade in the North American Free Trade Agreement (NAFTA) and the EU-15.

Driven largely by component trade, the share of intraregional nonoil trade in total world trade of ADEs increased continuously from about 20\% in 1985 to over $52 \%$ by 2008 (Figure 2). Until about the late 1990s, both intraregional trade shares of imports exports closely moved together. However, the time pattern has changed notably from then on. While the intraregional impost share has continued to increase at a faster rate, the intraregional export-to-GDP ratio virtually stagnated or recorded a mild decline in some years. Consequently, the rate of increase in total intraregional trade share has remarkably slowed. This notably asymmetry in the growth of intraregional exports and imports (and the consequent slow expansion in total intraregional trade) is a reflection of East Asia's unique role within global production networks, in particular the PRC's role as the premier assembly center within these networks based on parts and components procured from the rest of East Asia (Athukorala 2009).

## IV. Modelling Trade Flows

This section reports results of an econometric exercise undertaken to predict trade flows of the 12 countries to 2030 based on trade equations estimated at the country level using data for the period 1985 to 2008. The analytical tool used for this purpose is the gravity model, which has become the "workhorse" for modeling bilateral trade flows. The standard gravity model postulates that trade between two countries, like the gravitational
force between two masses, is a function of their economic size and the geographic distance between them. ${ }^{10}$ This basic model is augmented by adding a number of explanatory variables found in previous studies ${ }^{11}$ to improve the explanatory power of the estimated trade equations.

The specification of the gravity model is:

$$
\begin{gathered}
\operatorname{Ln}\left(X_{i, j} \text { or } M_{i, j}\right)=\alpha+\beta_{1} \ln \left(G D P_{i} G D P_{j}\right)+\beta_{2} \operatorname{InDST} T_{i, j}+\beta_{3} L N G_{i, j}+\beta_{4} A D J_{i, j}+ \\
\beta_{5} \ln R W G_{i, j}+\beta_{6} R T A_{i j,}+\beta_{7} C L N_{i j}+\beta_{8} D A F C+\beta_{9} D G F C+\gamma T+\varepsilon_{i j}
\end{gathered}
$$

Subscripts $i$ and $j$ refer to the reporter and the partner country in bilateral trade relation and the variables are listed and defined below, with the postulated sign of the regression coefficient for the explanatory variables in brackets.
$X$ or $M \quad$ Bilateral trade (export or import) between $i$ and $j$
GDP Real gross domestic product (GDP), a measure of the economic size (+)
DST Distance between the economic centers of $i$ and $j(-)$
LPI Index of the quality of trade-related logistics (LPI)
LNG Dummy variable that is unity if $i$ and $j$ have a common language and zero otherwise (+)

ADJ Dummy variable that is unity if $i$ and $j$ share the same border (+)
RTA Dummy that is unity if both $i$ and $j$ belong to the same referential trade agreement (RTA) (+)

CLN Dummy variable that is unity if $i$ and $j$ have a common language (a measure of cultural affinity) (+)

DAFC Binary dummy variable for the Asian financial crisis, 1997-1998
DGFC Binary dummy variable for the global financial crisis, 2008
$\alpha \quad$ Constant term
$T \quad$ Set of time dummy variables to capture year-specific "fixed" effects
$\varepsilon \quad$ Stochastic error term representing the omitted other influences on bilateral trade

[^10]Table 10: Share of Parts and Components in Trade Flows, 2006/7 (percent)

The model is estimated for each of the 12 Asian economies, separately for total exports and imports of merchandise trade (SITC 1 through 9), nonoil, and manufacturing trade (SITC 5 though 8 less 68). Trade data are from the Comtrade database. Data on GDP are extracted from the World Bank's World Development Indicators database. The nominal (US\$) trade data extracted from the Comtrade database are converted into real terms using US trade price indices extracted from the US Bureau of Labor Statistics database.

Data on LPI come from the newly developed Logistics Performance Index database of the World Bank (Arvis et al. 2007), which provides the first in-depth, cross-country assessment of trade-related logistic provisions. It covers 150 economies, including 28 in developing Asia. It is based on a worldwide survey of global freight forwarders and express carriers, complemented by a number of qualitative and quantitative indicators of the domestic logistics environment, institutions, and performance of supply chains. The data on bilateral distance come from the trade patterns database of the French Institute for Research on the International Economy (CEPII). The CEPII distance measure is a composite measure of the bilateral great-circle distance between major cities of each economy compiled by taking into account the trading significance of each city in each economy. Export shares for 2000 are used in compiling the distance measure for each economy. For a complete listing of variables and data sources see Appendix Table 1.

## A. Trade Equations

Of the three standard panel data estimation methods (pooled ordinary least squares [OLS], random effects, and fixed effects estimators), the fixed effect estimator is not appropriate in this case because the model contains a number of time-invariant explanatory variables that are central to the analysis. In experimental runs, both pooled OLS and random-effects estimators are used. The Bruesch-Pagan Lagrange multiplier test failed to reject the null hypothesis of random effects, favoring the use of pooled OLS estimator. The preferred (pooled OLS) estimates are reported in Table 12. Note that $P G D P_{1}$ and $P G D P_{\mathrm{J}}$ could not be retained in the final estimates because of their high correlation with the counterpart GDP variables. Common border dummy was deleted in the final estimates because of its high correlation with the distance variable.

The coefficients of the two standard gravity variables (GDP in pairs, and the distance) are statistically significant with the hypotheses signs in all cases. The coefficient of the distance variable is well within the range of $0.7-1.20$ commonly found in various gravity model applications. The coefficient of GDP in pairs is consistently closer to unity. The LPI performs remarkably well in explaining both imports and exports, with statistically significant and positive coefficients in all cases. The other control variables are not uniformly significant across all countries, both on import and export sides. These variables have been retained in a given equation only if the coefficients carried the expected sign with a t-ratio of more than unity. In terms of the overall fit the export equations generally performs better (with $R^{2} s$ of closer to 0.80 ) than the import equations ( $R^{2} s$ of around 0.65 ). As one would expect, estimated equations (both exports and imports) for nonoil trade generally exhibit a better overall fit compared to those for total trade.

## B. Trade Projections

The estimated equations are used for predicting trade flows for the period 2010-2030. The methodology involved estimating total trade for each country as the sum of bilateral trade flows estimated using the estimated import and export equations. In making these projections, GDP projections generated in this research project are used for the ADEs. GDP projections for the other trading partner countries of ADEs come from the USDA database.

Trade flow projections (US\$ billion) for total merchandise trade and nonoil merchandise trade for the ADEs are reported in Appendix Table 2. It is important note that these perditions are based on the assumption that the past trade patterns will continue unchanged for the ensuing 2 decades. In reality, the nature of trade orientation of an economy changes with the passage of time reflecting both structural changes in the domestic economy and changes in global trade patterns. The following discussion focuses on predictions for nonoil trade because the degree of dependence on oil and gas trade varies significantly among the countries.

Annual growth rates of projected trade flows are reported in Table 12. Total nonoil exports from ADEs are projected to grow at an annual rate of $7.9 \%$ during 2010-2020 and 9.9\% during 2020-2030 (Table 12, panel a). Predicted growth rates of imports for the two subperiods are $8.4 \%$ and $6.8 \%$, respectively. A comparison of the estimates on export and import sides points to a mild tendency for narrowing of the overall trade deficit of the region over the years. The annual growth rate of exports from the PRC is projected to decline from $10.4 \%$ during 2010-2020 to $8.1 \%$ between the 2 decades. Predicted import and export growth rates varies notably among the 12 economies, with significant slowing down of trade expansion in three NIEs (the Republic of Korea; Singapore; Taipei,China) compared to the other countries. Overall the estimates point to a notable convergence in the rate of trade expansion among the countries over the years.

Intraregional nonoil trade in ADEs are projected to grow at a slightly faster rate compared to their overall (global) trade (compare figures reported in Panel A and B in Table 12). Exports from these countries to regional markets during 2010-2030 will grow at $9.2 \%$ compared to $8.5 \%$ growth in the region's total exports. The comparable figures on the import side are $8.4 \%$ and $7.1 \%$, respectively. During these 2 decades the PRC's intraregional exports are protected to grow at 10.5\% compared to an overall export growth rate of $9.2 \%$. In all other countries intraregional trade would also grow at a faster rate compared to overall trade, driven by trade expansion associated with faster economic growth.

Reflecting these growth rate differentials between intraregional and total trade, intraregional share in total trade of ADEs will increase continuously during 2000-2030 (Table 13, Figure 3). Intraregional nonoil export share in ADEs would reach 64.9\% in 2030 from $56.9 \%$ in 2010. The increase on the import side would be from $53.5 \%$ to $59.5 \%$. Intraregional trade shares are predicted to increase in all countries in the region, with those of the second-tier ADEs increasing at a faster rate compared to the Republic of Korea; Singapore; and Taipei,China. The PRC's intraregional export and import shares are predicted to increase from $51.6 \%$ to $59.6 \%$, and $41.7 \%$ to $81.9 \%$, respectively, between 2010 and 2030.

Trade openness of the region, measured by the trade-to-GDP ratio, is projected to increase sharply from $39.4 \%$ in 2010 to $74.4 \%$ in 2030. Among the 12 economies, Hong Kong, China; Malaysia; Singapore; and the Philippines are notable for maintaining very high trade/GDP ratios for a long period of time (Krugman 1995). By the end of the projection period, Thailand and Viet Nam too are likely to join this group of "super trading economies". The PRC's degree of trade openness is projected to increase from $41.7 \%$ in 2010 to $81.9 \%$ in 2030. The degree of trade openness of India and Pakistan is projected to remain low compared to their East Asian counterparts. As already noted, these figures need to be treated with caution: they are based on the assumption that patterns of trade pertaining to the estimation period 1986-2008 will continue unchanged during the ensuing 2 decades. In particular, it is important to take into account the likely impact of the current policy emphasis in the PRC on rebalancing growth.

## V. Concluding Remarks

Developing Asian economies have become increasingly open to foreign trade and investment over the past 4 decades, but still there are notable contrasts patterns between East and South Asia, particularly between the PRC and India, notwithstanding converging growth rates. India and other South Asian countries have continued to remain underperformers.

Global production sharing has become an integral part of the economic landscape of East Asia. The degree of dependence on this new form of international specialization is proportionately larger in East Asia, in particular in the Association of Southeast Asian Nations (ASEAN), than in North America and Europe. A highly important recent development in international fragmentation of production has been the rapid integration of the PRC into the regional production networks. This development is an important counterpoint to the popular belief that the PRC's global integration would crowd out other countries' opportunities for international specialization. The PRC's imports of components from countries in ASEAN and other developing East Asia countries have grown rapidly, in line with the equally rapid expansion of manufacturing exports from the PRC to extraregional markets, mostly North America and Europe.

The PRC's emergence as a major trading power and an investment location is not a zero sum proposition from the perspective of the region. The PRC's rapid integration into regional production networks is an important counterpoint to the popular belief that its global integration would crowd out other countries' opportunities for international specialization. The PRC's imports of components from countries in ASEAN and other developing East Asian countries have grown rapidly, in line with the equally rapid expansion of manufacturing exports from the PRC to extraregional markets, mostly North America and Europe. The PRC's pivotal role with regional production networks also seems to have added further dynamism to regionwide MNE operations. The migration of some production processes within vertically integrated high-tech industries to the PRC opens up opportunities for producing original-equipment-manufactured goods and backoffice service operations in other countries. Even if the PRC continues to remain relatively attractive as an assembly center, not all stages of production within vertically integrated global industries are going to move there; supply chain managers are reluctant to source all of their inputs from just one nation, preferring instead to diversify the risk of exchange rate instability or supply disruptions. There is also evidence that rapid growth in wages has already begun to erode some of the PRC's cost advantages, encouraging firms in the PRC to relocate labor-intensive manufacturing activities to low-wage countries in the region.

A notable outcome of the rapid expansion of production networks has been the rapid growth of cross-border trade in parts and components within the regions; component share in intra-ADE trade is much higher compared to that of intraregional trade in NAFTA
and EU-15. Driven largely by cross-border component trade, the share of intraregional nonoil trade in total world trade of ADEs increased continuously from about $20 \%$ in 1985 to over $52 \%$ by 2008. The intraregional share of imports has increased at a much faster rate compared to the intraregional share of exports, reflecting ADEs' unique role within global production networks, in particular the PRC's role as the premier assembly center within these networks based on components procured from the other countries in the region.

According to projections based on the standard gravity modelling framework, total nonoil exports and imports from ADEs would increase at an annual rate of $8.5 \%$ and $7.8 \%$ during 2010-2030, exhibiting a mild slowdown in the rate of growth over time. The growth of intraregional trade would be about 1.2 percentage points faster, resulting in an increase in intraregional share in total exports and imports of countries in the region from $53.5 \%$ to $9.5 \%$, and $56.9 \%$ to $63.3 \%$, respectively. Trade openness of the region, measured by the trade-to-GDP ratio, is projected to increase from $39.4 \%$ in 2010 to $74.4 \%$ in 2030. These predictions need to be treated with caution as they are based on the assumption that patterns of trade pertaining to the estimation period 1986-2008 will continue unchanged during the ensuing 2 decades.

## Appendix: Trade Data Compilation

The data used in the analysis of trends and patterns trade flows for all economies other than Taipei,China are compiled from the UN Comtrade database, based on Revision 3 of the Standard International Trade Classification (SITC, Rev. 3). Data for Taipei,China are obtained from the trade database (based on the same classification system) of the Council for Economic Planning and Development.

To analyze the growing importance of regional production networks in determining trade patterns, detailed ( 5 -digit) data for the period 1992-2008 are used. Although the SITC Rev. 3 was introduced in the mid-1980s, a close examination of country-level data shows that data recording systems in many countries had considerable gaps in the coverage parts and components trade until the early 1990s. Therefore 1992 is used as the starting year for data disaggregation.

In previous studies of international production fragmentation and trade patterns (e.g., Ng and Yeats 2003, Athukorala 2005, Athukorala and Yamashita 2008) commodity coverage was limited to parts and components, which can be directly identifiable based on the commodity nomenclature of the US Standard International Trade Classification (SITC). These items are confined to the product classes of machinery and transport equipment (SITC 7) and SITC 8. However, there is evidence that global production sharing has been spreading beyond SITC 7 and 8 to other product categories, such as pharmaceutical and chemical products (SITC 5) and machine tools and various metal products (SITC 6). This study uses a list of parts and components encompassing the entire spectrum of manufacturing trade. The list was compiled by mapping parts and components in the UN Broad Economic Classification (BEC) Registry (available at http:/www. unstats.un.org/ unsd/cr/registry) in the product list of the WTO Information Technology Agreement with the Harmonized System (HS) of trade classification at the 6-digit level. Information gathered from firmlevel surveys conducted in Malaysia and Thailand as part of this author's ongoing research in this field was used to fill gaps in the list. Data compiled at the HS 6-digit level were converted to SITC for the final analysis using the UN HS-SITC concordance.

There is no hard and fast rule applicable to distinguishing between parts and components and assembled products in international trade data. The only practical way of doing this is to focus on the specific industries in which network trade is heavily concentrated. Once these industries are identified, assembly trade can be tentatively estimated as the difference between parts and components, directly identified based on the list here, and recorded trade in these product categories (Krugman 2008). This is the procedure followed here. Guided by the available literature on production sharing, seven product categories are identified: office machines and automatic data processing machines (SITC 75), telecommunication and sound recording equipment (SITC 76), semiconductors and semiconductor devices (SITC 772 and 776), electrical goods (SITC 77-772-776), road vehicles (SITC 78), professional and scientific equipment (SITC 87), and photographic apparatus (SITC 88). It is quite reasonable to assume that these product categories contain virtually no products produced from start to finish in a given country. Admittedly however, the estimates based on this list do not provide a full coverage of final assembly in world trade. For instance, outsourcing of final assembly does takes place in various miscellaneous product categories such as clothing, furniture, sport goods, and leather products. However, it is not possible to meaningfully delineate parts and components and assembled goods in reported trade in these product categories because they contain a significant (though unknown) share of "horizontal" trade. Likewise, assembly activities in software trade have recorded impressive expansion in recent years, but these are lumped together in the UN data system with "special transactions" under SITC 9. However, the magnitude of the bias resulting from the failure to
cover these items is unlikely to be substantial because network trade in final assembly is heavily concentrated in the product categories covered in the decomposition.

The data are tabulated using importer records, which are considered to be more appropriate for analyzing trade patterns than the corresponding exporter records. It is generally believed that data compiled from importer records are less susceptible to recording errors, and reveal the origins and composition of trade more accurately than other records, because there are normally important legal penalties for incorrectly specifying this information on customs declarations. Importer records are also presumably less susceptible to double-counting and erroneous identification of the source/ destination country in the presence of entrepot trade, for example, the PRC's trade through Hong Kong, China; and Indonesia's trade through Singapore ( Ng and Yeats 2003, Feenstra et al. 2005).

## Appendix Table 1: Variables Construction and Data Sources for Gravity Model Estimation

| Label | Definition | Data Source/Variable Construction |
| :--- | :--- | :--- |
| X, M | Value of bilateral trade (imports and exports) in <br> US\$ measured at constant (2000) prices. | Exports (at CIF price, US\$): compiled from <br> importer records of UN-COMTRADE online <br> database. Exports and import values are deflated <br> by US import and export price indices extracted <br> from the US Bureau of Labor Statistics database. |
| GDP, GDPP | Real GDP and real per capita GDP (at 1995 price) | World Development Indicators, The World Bank |
| DIST | Weighted distance measure of the French <br> Institute for Research on the International <br> Economy (CEPII), which measures the bilateral <br> great-circle distance between major cities of each <br> country | CEPII database |
| World Bank logistic performance index Arvis et <br> al. (2007) | LPI database, World Bank |  |
| LPI | A dummy variable which is unity if $i$ and $j$ have a <br> common language and is zero | CEPII database |
| LNG | A binary dummy variables that takes the value 1 <br> for countries sharing a common land border, and <br> 0 otherwise | CEPII database |

## About the Paper

Prema-chandra Athukorala provides trade flow projections for major Asian developing economies (ADEs) for the next 2 decades against the backdrop of an in-depth analysis of policy shifts and trade patterns over the past 4 decades. Total real nonoil trade of ADEs is predicted to increase at an average annual rate of 8.2 \% during the next two decades, with a notable convergence of individual countries' rates to the regional average. The share of intraregional trade in total nonoil trade would increase steadily from 53\% in 2010 to 58\% in 2030.

## About the Asian Development Bank

ADB's vision is an Asia and Pacific region free of poverty. Its mission is to help its developing member countries reduce poverty and improve the quality of life of their people. Despite the region's many successes, it remains home to two-thirds of the world's poor: 1.8 billion people who live on less than $\$ 2$ a day, with 903 million struggling on less than $\$ 1.25$ a day. ADB is committed to reducing poverty through inclusive economic growth, environmentally sustainable growth, and regional integration.

Based in Manila, ADB is owned by 67 members, including 48 from the region. Its main instruments for helping its developing member countries are policy dialogue, loans, equity investments, guarantees, grants, and technical assistance.

[^2]:    Prema-chandra Athukorala is Professor of Economics, Arndt-Corden Department of Economics, Crawford School of Economics and Government, College of Asia and the Pacific, Australian National University. The author is grateful to Archanun Kohpaiboon for an excellent job done in collating/tabulating trade data, to Majeed and Shahbaz Naseer for invaluable help with econometrics, and to Shin-Ichi Fukuda and other participants of the Long-term Projections of Asian GDP and Trade Workshop held at The Chinese University of Hong Kong, 8-9 July 2010, for very helpful comments on the draft paper. This paper was prepared under the Asian Development Bank's TA7470-REG: Long-term Projections of Asian GDP and Trade. The author accepts responsibility for any errors in the paper.

[^3]:    3 See Table 2, Note 1 for the criteria used in identifying the year of demarcation. The original Sachs-Warner classification covered 100 countries ( 78 developing and 22 developed countries) over the period 1945-1994. Wacziarg and Welch (2003) have updated the classification to 2000, while expanding the coverage to 131 countries.

[^4]:    4 After the PRC's accession to membership in January 2001 and Viet Nam in January 2006, all 12 ADEs are now bound by WTO multilateral disciple.

[^5]:    5 Exports are generally regarded as preferable to total trade (or imports) as the numerator in calculating this ratio because restrictiveness of a given country's policy regime is presumably better captured by export performance.

[^6]:    6 Trade data throughout the paper are measured in current US dollars unless otherwise indicated.
    7 Oil and gas account for a significant (albeit declining) share in export only in Indonesia, Malaysia, and Singapore.
    8 In this and other trade data tables, data are presented as 2 -year averages to smooth out the impact of yearly fluctuations in trade.
