Abstract

We analyze linear panel regression models with interactive fixed effects and predetermined regressors, e.g. lagged-dependent variables. The first order asymptotic theory of the least squares (LS) estimator of the regression coefficients is worked out in the limit where both the cross sectional dimension and the number of time periods become large. We find that there are two sources of asymptotic bias of the LS estimator: bias due to correlation or heteroscedasticity of the idiosyncratic error term, and bias due to predetermined (as opposed to strictly exogenous) regressors. A bias corrected least squares estimator is provided. We also present bias corrected versions of the three classical test statistics (Wald, LR and LM test) and show that their asymptotic distribution is a χ^2 -distribution. Monte Carlo simulations show that the bias correction of the LS estimator and of the test statistics also work well for finite sample sizes.

1 Introduction

In this paper we study a linear panel regression model where the individual fixed effects λ_i , called factor loadings, interact with common time specific effects f_t , called factors. This interactive fixed effect specification contains the conventional fixed effects and time-specific effects as special cases, but is significantly more flexible since it allows the factors f_t to affect each individual with a different loading λ_i .

Factor models have been widely studied in various economics disciplines, for example in asset pricing, forecasting, empirical macro and empirical labor economics.¹ In the panel literature, factor models are often used to represent time varying individual effects (or heterogenous time effects), so called interactive fixed effects. For panels with a large cross sectional dimension (N) but a short time dimension (T), Holtz-Eakin, Newey, and Rosen (1988) (hereafter HNR) study a linear panel regression model with interactive fixed effects and lagged dependent variables. To solve the incidental parameter problem caused by the λ_i 's, they estimate a quasi-differenced version of the model using appropriate lagged variables as instruments, and treating f_t 's as a fixed number of parameters to estimate. Ahn, Lee and Schmidt (2001) also consider large N but short T panels. Instead of eliminating the individual effects λ_i by transforming the panel data, they impose various second moment restrictions including the correlated random effects λ_i , and derive moment conditions to estimate the regression coefficients. More recent literature considers panels with comparable size of N and T . The interactive fixed effect panel regression model of Pesaran (2006) allows heterogenous regression coefficients. Pesaran's estimator is the common correlated effect (CCE) estimator that uses the cross sectional averages of the dependent variable and the independent variables as control functions for the interactive fixed effects.²

Among the interactive fixed effect panel literature, most closely related to our paper is Bai (2009). Bai assumes that the regressors are *strictly* exogenous and the number of factors is known. The estimator that he investigates is the least squares (LS) estimator, which minimizes the sum of squared residuals of the model jointly over the regression coefficients and the fixed effect parameters λ_i and f_t .³ Using the alternative asymptotic where $N, T \rightarrow \infty$ at the same rate,⁴ Bai shows that the LS estimator is \sqrt{NT} -consistent and asymptotically normal, but may have an asymptotic bias. The bias in the normal limiting distribution occurs when the regression errors are correlated or heteroscedastic. Bai also shows how to estimate the bias and proposes a bias corrected estimator.

Following the methodology in Bai (2009), we investigate the LS estimator for a linear panel

regression with a known number of interactive fixed effects. The main difference from Bai is that we consider *predetermined* regressors, thus allowing feedback of past outcomes to future regressors. One of the main findings of the present paper is that the limit distribution of the LS estimator has two types of biases, one type of bias due to correlated or heteroscedastic errors (the same bias as in Bai) and the other type of bias due to the predetermined regressors. This additional bias term is analogous to the incidental parameter bias of Nickell (1981) in finite T and the bias in Hahn and Kuersteiner (2002) in large T .

In addition to allowing for predetermined regressors, we also extend Bai’s results to models where both “low-rank regressor” (e.g. time-invariant and common regressors, or interactions of those two) and “high-rank-regressor” (almost all other regressors that vary across individuals and over time) are present simultaneously, while Bai (2009) only considers the “low-rank regressor” separately and in a restrictive setting (in particular not allowing for regressors that are obtained by interacting time-invariant and common variables). A general treatment of “low-rank regressors” is desirable since they often occur in applied work, e.g., Gobillon and Magnac (2013). The analysis of those regressors is challenging, however, since the unobserved interactive fixed effects also represent a low-rank $N \times T$ matrix, thus posing a non-trivial identification problem for low-rank regressors, which needs to be addressed. We provide conditions under which the different type of regressors are identified jointly and under which they can be estimated consistently as N and T grow large.

Another contribution of this paper is to establish the asymptotic theory of the three classical test statistics (Wald test, LR test, and LM (or score) test) for testing restrictions on the regression coefficients in a large N , T panel framework.⁵ Regarding testing for coefficient restrictions, Bai (2009) investigates the Wald test based on the bias corrected LS estimator, and HNR consider the LR test in their 2SLS estimation framework with fixed T .⁶ What we show is that the conventional LR and LM test statistics based on the LS profile objective function have non-central chi-square limit due to incidental parameters in the interactive fixed effects. We therefore propose modified LR and LM tests whose asymptotic distributions are conventional chi-square distributions.

In order to establish the asymptotic theories of the LS estimator and the three classical tests, we use the quadratic approximation of the profile LS objective function that was derived in Moon and Weidner (2013). This method is different from Bai (2009), who uses the first order condition of the LS optimization problem as the starting point of his analysis. One advantage of our methodology is that it can also directly be applied to derive the asymptotic properties of the LR and LM test statistics.

In this paper, we assume that the regressors are not endogenous and the number of factors is known, which might be restrictive in some applications. In other papers we study how to relax these restrictions. Moon and Weidner (2013) investigates the asymptotic properties of the LS estimator of the linear panel regression model with factors when the number of factors is unknown and extra factors are included unnecessarily in the estimation. It turns out that under suitable conditions the limit distribution of the LS estimator is unchanged when the number of factors is overestimated. Moon and Weidner (2013) is complementary to the current paper, since there we do not derive the limiting distribution of the estimator, do not correct for the bias, and also do not consider low-rank regressors or testing problems. The extension to allow endogenous regressors is closely related with the result in Moon, Shum and Weidner (2012) (hereafter MSW). MSW's main purpose is to extend the random coefficient multinomial logit demand model (known as the BLP demand model from Berry, Levinsohn and Pakes (1995)) by allowing for interactive product and market specific fixed effects. Although the main model of interest is quite different from the linear panel regression model of the current paper, MSW's econometrics framework is directly applicable to the model of the current paper with endogenous regressors. In Section 6, we briefly discuss how to apply the estimation method of MSW in the current framework with endogenous regressors.⁷

Comparing the different estimation approaches for interactive fixed effect panel regressions proposed in the literature, it seems fair to say that the LS estimator in Bai (2009) and our paper, the CCE estimator of Pesaran (2006), and the IV estimator based on quasi-differencing in HNR, all have their own relative advantages and disadvantages. These three estimation methods handle the interactive fixed effects quite differently. The LS method concentrates out the interactive fixed effects by taking out the principal components. The CCE method controls the factor (or time effects) using the cross sectional averages of the dependent and independent variables. The HNR's approach quasi-differences out the individual effects, treating the remaining time effects as parameters to estimate. The IV estimator of HNR should work well when T is short, but should be expected to also suffer from an incidental parameter problem due to estimation of the factors when T becomes large. Pesaran's CCE estimation method does not require the number of factors to be known and does not require the strong factor assumption that we will impose below, but in order for the CCE to work, not only the DGPs for the dependent variable (e.g., the regression model) but also the DGP of the explanatory variables should be restricted in a way that their cross sectional average can control the unobserved factors. The LS estimator and its bias corrected version perform well under relatively weak restrictions on the regressors, but it requires that T should not be too small and the factors should be sufficiently

strong to be correctly picked up as the leading principal components.

The paper is organized as follows. In Section 2 we introduce the interactive fixed effect model and provide conditions for identifying the regression coefficients in the presence of the interactive fixed effects. In Section 3 we define the LS estimator of the regression parameters and provide a set of assumptions that are sufficient to show consistency of the LS estimator. In Section 4 we work out the asymptotic distribution of the LS estimator under the alternative asymptotic. We also provide a consistent estimator for the asymptotic bias and a bias corrected LS estimator. In Section 5 we consider the Wald, LR and LM tests for testing restrictions on the regression coefficients of the model. We present bias corrected versions of these tests and show that they have chi-square limiting distribution. In Section 6 we briefly discuss how to estimate the interactive fixed effect linear panel regression when the regressors are endogenous. In Section 7 we present Monte Carlo simulation results for an AR(1) model with interactive fixed effect. The simulations show that the LS estimator for the AR(1) coefficient is biased, and that the tests based on it can have severe size distortions and power asymmetries, while the bias corrected LS estimator and test statistics have better properties. We conclude in Section 8. All proofs of theorems and some technical details are presented in the appendix or supplementary material.

A few words on notation. For a column vector v the Euclidean norm is defined by $\|v\| = \sqrt{v'v}$. For the n -th largest eigenvalues (counting multiple eigenvalues multiple times) of a symmetric matrix B we write $\mu_n(B)$. For an $m \times n$ matrix A the Frobenius norm is $\|A\|_F = \sqrt{\text{Tr}(AA')}$, and the spectral norm is $\|A\| = \max_{0 \neq v \in \mathbb{R}^n} \frac{\|Av\|}{\|v\|}$, or equivalently $\|A\| = \sqrt{\mu_1(A'A)}$. Furthermore, we define $P_A = A(A'A)^\dagger A'$ and $M_A = \mathbb{I} - A(A'A)^\dagger A'$, where \mathbb{I} is the $m \times m$ identity matrix, and $(A'A)^\dagger$ is the Moore-Penrose pseudoinverse, to allow for the case that A is not of full column rank. For square matrices B, C , we write $B > C$ (or $B \geq C$) to indicate that $B - C$ is positive (semi) definite. For a positive definite symmetric matrix A we write $A^{1/2}$ and $A^{-1/2}$ for the unique symmetric matrices that satisfy $A^{1/2}A^{1/2} = A$ and $A^{-1/2}A^{-1/2} = A^{-1}$. We use ∇ for the gradient of a function, i.e. $\nabla f(x)$ is the column vector of partial derivatives of f with respect to each component of x . We use “wpa1” for “with probability approaching one”.

2 Model and Identification

We study the following panel regression model with cross-sectional size N , and T time periods,

$$Y_{it} = \beta^{0'} X_{it} + \lambda_i^{0'} f_t^0 + e_{it}, \quad i = 1 \dots N, \quad t = 1 \dots T, \quad (1)$$

where X_{it} is a $K \times 1$ vector of observable regressors, β^0 is a $K \times 1$ vector of regression coefficients, λ_i^0 is an $R \times 1$ vector of unobserved factor loadings, f_t^0 is an $R \times 1$ vector of unobserved common factors, and e_{it} are unobserved errors. The superscript zero indicates the true parameters. We write f_{tr}^0 and λ_{ir}^0 , where $r = 1, \dots, R$, for the components of λ_i^0 and f_t^0 , respectively. R is the number of factors. Note that we can have $f_{tr}^0 = 1$ for all t and a particular r , in which case the corresponding λ_{ir}^0 become standard individual specific effects. Analogously we can have $\lambda_{ir}^0 = 1$ for all i and a particular r , so that the corresponding f_{tr}^0 become standard time specific effects.

Throughout this paper we assume that the true number of factors R is known.⁸ We introduce the notation $\beta^0 \cdot X = \sum_{k=1}^K \beta_k^0 X_k$. In matrix notation the model can then be written as

$$Y = \beta^0 \cdot X + \lambda^0 f^{0r} + e ,$$

where Y , X_k and e are $N \times T$ matrices, λ^0 is an $N \times R$ matrix, and f^0 is a $T \times R$ matrix. The elements of X_k are denoted by $X_{k,it}$.

We separate the K regressors into K_1 ‘‘low-rank regressors’’ X_l , $l = 1, \dots, K_1$, and $K_2 = K - K_1$ ‘‘high-rank regressors’’ X_m , $m = K_1 + 1, \dots, K$. Each low-rank regressor $l = 1, \dots, L$ is assumed to satisfy $\text{rank}(X_l) = 1$. This implies that we can write $X_l = w_l v_l'$, where w_l is an N -vector and v_l is a T -vector, and we also define the $N \times K_1$ matrix $w = (w_1, \dots, w_{K_1})$ and the $T \times K_1$ matrix $v = (v_1, \dots, v_{K_1})$.

Let $l = 1, \dots, K_1$. The two most prominent types of low-rank regressors are time-invariant regressors, which satisfy $X_{l,it} = Z_i$ for all i, t , and common (or cross-sectionally invariant) regressors, in which case $X_{l,it} = W_t$ for all i, t . Here, Z_i and W_t are some observed variables, which only vary over i or t , respectively. A more general low-rank regressor can be obtained by interacting Z_i and W_t multiplicatively, i.e. $X_{l,it} = Z_i W_t$, an empirical example of which is given in Gobillon and Magnac (2013). In these examples, and probably for the vast majority of applications, the low-rank regressors all satisfy $\text{rank}(X_l) = 1$, but our results can easily be extended to more general low-rank regressors.⁹

High-rank regressor are those whose distribution guarantees that they have high rank (usually full rank) when considered as an $N \times T$ matrix. For example, a regressor whose entries satisfy $X_{m,it} \sim iid\mathcal{N}(\mu, \sigma)$, with $\mu \in \mathbb{R}$ and $\sigma > 0$, satisfies $\text{rank}(X_m) = \min(N, T)$ with probability one.

This separation of the regressors into low- and high-rank regressors is important to formulate our assumptions for identification and consistency, but actually plays no role in the estimation

and inference procedures for $\widehat{\beta}$ discussed below.

Assumption ID (Assumptions for Identification).

(i) Existence of Second Moments:

The second moments of $X_{k,it}$ and e_{it} conditional on λ^0, f^0, w exist for all i, t, k .

(ii) Mean Zero Errors and Exogeneity:

$\mathbb{E}(e_{it}|\lambda^0, f^0, w) = 0, \mathbb{E}(X_{k,it}e_{it}|\lambda^0, f^0, w) = 0$, for all i, t, k .

The following two assumptions only need to be imposed if $K_1 > 0$, i.e. if low-rank regressors are present:

(iii) Non-Collinearity of Low-Rank Regressors:

Consider linear combinations $\alpha \cdot X_{\text{low}} = \sum_{l=1}^{K_1} \alpha_l X_l$ of the low-rank regressors X_l with $\alpha \in \mathbb{R}^{K_1}$. For all $\alpha \neq 0$ we assume that

$$\mathbb{E}[(\alpha \cdot X_{\text{low}})M_{f^0}(\alpha \cdot X_{\text{low}})'|\lambda^0, f^0, w] \neq 0.$$

(iv) No Collinearity between Factor Loadings and Low-Rank Regressors:

$$\text{rank}(M_w \lambda^0) = \text{rank}(\lambda^0).^{10}$$

The following assumption only needs to be imposed if $K_2 > 0$, i.e. if high-rank regressors are present:

(v) Non-Collinearity of High-Rank Regressors:

Consider linear combinations $\alpha \cdot X_{\text{high}} = \sum_{m=K_1+1}^K \alpha_m X_m$ of the high-rank regressors X_m for $\alpha \in \mathbb{R}^{K_2}$, where the components of the K_2 -vector α are denoted by α_{K_1+1} to α_K . For all $\alpha \neq 0$ we assume that

$$\text{rank} \{ \mathbb{E}[(\alpha \cdot X_{\text{high}})(\alpha \cdot X_{\text{high}})'|\lambda^0, f^0, w] \} > 2R + K_1.$$

All expectations in the assumptions are conditional on λ^0, f^0 , and w , in particular e_{it} is not allowed to be correlated with λ^0, f^0 , and w . However, e_{it} is allowed to be correlated with v (i.e. predetermined low-rank regressors are allowed). If desired, one can interchange the role of N and T in the assumptions, by using the formal symmetry of the model under exchange of the panel dimensions ($N \leftrightarrow T, \lambda^0 \leftrightarrow f^0, Y \leftrightarrow Y', X_k \leftrightarrow X'_k, w \leftrightarrow v$).

Assumptions ID(i) and (ii) have standard interpretations, but the other assumptions require some further discussion.

Assumption ID(*iii*) states that the low-rank regressors are non-collinear even after projecting out all variation that is explained by the true factors f^0 . This would, for example, be violated if $v_l = f_r^0$ for some $l = 1, \dots, K_1$ and $r = 1, \dots, R$, since then $X_l M_{f^0} = 0$ and we can choose α such that $X_{\text{low}} = X_l$. Similarly, Assumption ID(*iv*) rules out, for example, that $w_l = \lambda_r^0$ for some $l = 1, \dots, K_1$ and $r = 1, \dots, R$, since then $\text{rank}(M_w \lambda^0) < \text{rank}(\lambda^0)$, in general. It ought to be expected that λ^0 and f^0 have to feature in the identification conditions for the low-rank regressors, since the interactive fixed effects structure and the low-rank regressors represent similar types of low-rank $N \times T$ structures.

Assumption ID(*v*) is a generalized non-collinearity assumption for the high-rank regressors, which guarantees that any linear combination $\alpha \cdot X_{\text{high}}$ of the high-rank regressors is sufficiently different from the low-rank regressors and from the interactive fixed effects. A standard non-collinearity assumption can be formulated by demanding that the $N \times N$ matrix $\mathbb{E}[(\alpha \cdot X_{\text{high}})(\alpha \cdot X_{\text{high}})' | \lambda^0, f^0, w]$ is non-zero for all non-zero $\alpha \in \mathbb{R}^{K_2}$, which can be equivalently expressed as $\text{rank}\{\mathbb{E}[(\alpha \cdot X_{\text{high}})(\alpha \cdot X_{\text{high}})' | \lambda^0, f^0, w]\} > 0$ for all non-zero $\alpha \in \mathbb{R}^{K_2}$. Assumption ID(*v*) strengthens this standard non-collinearity assumption by demanding the rank not only to be positive, but larger than $2R + K_1$. This also explains the name ‘‘high-rank regressors’’, since their rank has to be sufficiently large in order to satisfy this assumption. Note also that only the number of factors R , but not λ^0 and f^0 itself feature in Assumption ID(*v*). The sample version of this assumption is given by Assumption 4(*ii*)(*a*) below, which is also very closely related to Assumption A in Bai (2009).

Theorem 2.1 (Identification). *Suppose that the Assumptions ID are satisfied. Then, the minima of the expected objective function $\mathbb{E}\left(\|Y - \beta \cdot X - \lambda f'\|_F^2 \mid \lambda^0, f^0, w\right)$ over $(\beta, \lambda, f) \in \mathbb{R}^{K+N \times R+T \times R}$ satisfy $\beta = \beta^0$ and $\lambda f' = \lambda^0 f^{0'}$. This shows that β^0 and $\lambda^0 f^{0'}$ are identified.*

The theorem shows that the true parameters are identified as minima of the expected value of $\|Y - \beta \cdot X - \lambda f'\|_F^2 = \sum_{i,t} (Y_{it} \beta' - X_{it} - \lambda'_i f_t)^2$, which is the sum of squared residuals. The same objective function is used to define the estimators $\widehat{\beta}$, $\widehat{\lambda}$ and \widehat{f} below. Without further normalization conditions the parameters λ^0 and f^0 are not separately identified, because the outcome variable Y is invariant under transformations $\lambda^0 \rightarrow \lambda^0 A'$ and $f^0 \rightarrow f^0 A^{-1}$, where A is a non-singular $R \times R$ matrix. However, the product $\lambda^0 f^{0'}$ is uniquely identified according to the theorem. Since our focus is on identification and estimation of β^0 , there is no need to discuss those additional normalization conditions for λ^0 and f^0 in this paper.

3 Estimator and Consistency

The objective function of the model is simply the sum of squared residuals, which in matrix notation can be expressed as

$$\begin{aligned} \mathcal{L}_{NT}(\beta, \lambda, f) &= \frac{1}{NT} \|Y - \beta \cdot X - \lambda f'\|_F^2 \\ &= \frac{1}{NT} \text{Tr} [(Y - \beta \cdot X - \lambda f')' (Y - \beta \cdot X - \lambda f')] . \end{aligned} \quad (2)$$

The estimator we consider is the LS estimator that jointly minimizes $\mathcal{L}_{NT}(\beta, \lambda, f)$ over β , λ and f . Our main object of interest are the regression parameters $\beta = (\beta_1, \dots, \beta_K)'$, whose estimator is given by

$$\hat{\beta} = \underset{\beta \in \mathbb{B}}{\text{argmin}} L_{NT}(\beta) , \quad (3)$$

where $\mathbb{B} \subset \mathbb{R}^K$ is a compact parameter set that contains the true parameter, i.e. $\beta^0 \in \mathbb{B}$, and the objective function is the profile objective function

$$\begin{aligned} L_{NT}(\beta) &= \min_{\lambda, f} \mathcal{L}_{NT}(\beta, \lambda, f) \\ &= \min_f \frac{1}{NT} \text{Tr} [(Y - \beta \cdot X) M_f (Y - \beta \cdot X)'] \\ &= \frac{1}{NT} \sum_{r=R+1}^T \mu_r [(Y - \beta \cdot X)' (Y - \beta \cdot X)] . \end{aligned} \quad (4)$$

Here, the first expression for $L_{NT}(\beta)$ is its definition as the the minimum value of $\mathcal{L}_{NT}(\beta, \lambda, f)$ over λ and f . We denote the minimizing incidental parameters by $\hat{\lambda}(\beta)$ and $\hat{f}(\beta)$, and we define the estimators $\hat{\lambda} = \hat{\lambda}(\hat{\beta})$ and $\hat{f} = \hat{f}(\hat{\beta})$. Those minimizing incidental parameters are not uniquely determined – for the same reason that λ^0 and f^0 are non uniquely identified –, but the product $\hat{\lambda}(\beta)\hat{f}'(\beta)$ is unique.

The second expression for $L_{NT}(\beta)$ in equation (4) is obtained by concentrating out λ (analogously, one can concentrate out f to obtain a formulation where only the parameter λ remains). The optimal f in the second expression is given by the R eigenvectors that correspond to the R largest eigenvalues of the $T \times T$ matrix $(Y - \beta \cdot X)' (Y - \beta \cdot X)$. This leads to the third line that presents the profile objective function as the sum over the $T - R$ smallest eigenvalues of this $T \times T$ matrix. Lemma A.1 in the appendix shows equivalence of the three expressions for $L_{NT}(\beta)$ given above.

Multiple local minima of $L_{NT}(\beta)$ may exist, and one should use multiple starting values for the numerical optimization of β to guarantee that the true global minimum $\hat{\beta}$ is found.

To show consistency of the LS estimator $\widehat{\beta}$ of the interactive fixed effect model, and also later for our first order asymptotic theory, we consider the limit $N, T \rightarrow \infty$. In the following we present assumptions on X_k , e , λ , and f that guarantee consistency.¹¹

Assumption 1. (i) $\text{plim}_{N,T \rightarrow \infty} (\lambda^{0'} \lambda^0 / N) > 0$, (ii) $\text{plim}_{N,T \rightarrow \infty} (f^{0'} f^0 / T) > 0$.

Assumption 2. $\text{plim}_{N,T \rightarrow \infty} [(NT)^{-1} \text{Tr}(X_k e')] = 0$, for all $k = 1, \dots, K$.

Assumption 3. $\text{plim}_{N,T \rightarrow \infty} (\|e\| / \sqrt{NT}) = 0$.

Assumption 1 guarantees that the matrices f^0 and λ^0 have full rank, i.e. that there are R distinct factors and factor loadings asymptotically, and that the norm of each factor and factor loading grows at a rate of \sqrt{T} and \sqrt{N} , respectively. Assumption 2 demands that the regressors are weakly exogenous. Assumption 3 restricts the spectral norm of the $N \times T$ error matrix e . We discuss this assumption in more detail in the next section, and we give examples of error distributions that satisfy this condition in Section S.2 of the supplementary material. The final assumption needed for consistency is an assumption on the regressors X_k . We already introduced the distinction between the K_1 “low-rank regressors” X_l , $l = 1, \dots, K_1$, and the $K_2 = K - K_1$ “high-rank regressors” X_m , $m = K_1 + 1, \dots, K$ above.

Assumption 4.

(i) $\text{plim}_{N,T \rightarrow \infty} \left[(NT)^{-1} \sum_{i=1}^N \sum_{t=1}^T X_{it} X'_{it} \right] > 0$.

(ii) *The two types of regressors satisfy:*

(a) *Consider linear combinations $\alpha \cdot X_{\text{high}} = \sum_{m=K_1+1}^K \alpha_m X_m$ of the high-rank regressors X_m for K_2 -vectors α with $\|\alpha\| = 1$, where the components of the K_2 -vector α are denoted by α_{K_1+1} to α_K . We assume that there exists a constant $b > 0$ such that*

$$\min_{\{\alpha \in \mathbb{R}^{K_2}, \|\alpha\|=1\}} \sum_{r=2R+K_1+1}^N \mu_r \left[\frac{(\alpha \cdot X_{\text{high}})(\alpha \cdot X_{\text{high}})'}{NT} \right] \geq b \quad \text{wpa1.}$$

(b) *For the low-rank regressors we assume $\text{rank}(X_l) = 1$, $l = 1, \dots, K_1$, i.e. they can be written as $X_l = w_l v'_l$ for N -vectors w_l and T -vectors v_l , and we define the $N \times K_1$ matrix $w = (w_1, \dots, w_{K_1})$ and the $T \times K_1$ matrix $v = (v_1, \dots, v_{K_1})$. We assume that there exists a constant $B > 0$ such that $N^{-1} \lambda^{0'} M_w \lambda^0 > B \mathbb{I}_R$ and $T^{-1} f^{0'} M_v f^0 > B \mathbb{I}_R$, wpa1.*

Assumption 4(i) is a standard non-collinearity condition for all the regressors. Assumption 4(ii)(a) is an appropriate sample analog of the identification Assumption ID(v). If the sum in Assumption 4(ii)(a) would start from $r = 1$, then we would have $\sum_{r=1}^N \mu_r \left[\frac{(\alpha \cdot X_{\text{high}})(\alpha \cdot X_{\text{high}})'}{NT} \right] = \frac{1}{NT} \text{Tr}[(\alpha \cdot X_{\text{high}})(\alpha \cdot X_{\text{high}})']$, so that the assumption would become a standard non-collinearity condition. Not including the first $2R + K_1$ eigenvalues in the sum implies that the $N \times N$ matrix $(\alpha \cdot X_{\text{high}})(\alpha \cdot X_{\text{high}})'$ needs to have rank larger than $2R + K_1$.

Assumption 4(ii)(b) is closely related to the identification Assumptions ID(iii) and (iv). The appearance of the factors and factor loadings in this assumption on the low-rank regressors is inevitable in order to guarantee consistency. For example, consider a low-rank regressor that is cross-sectionally independent and proportional to the r 'th unobserved factor, e.g. $X_{l,it} = f_{tr}$. The corresponding regression coefficient β_l is then not identified, because the model is invariant under a shift $\beta_l \mapsto \beta_l + a$, $\lambda_{ir} \mapsto \lambda_{ir} - a$, for an arbitrary $a \in \mathbb{R}$. This phenomenon is well known from ordinary fixed effect models, where the coefficients of time-invariant regressors are not identified. Assumption 4(ii)(b) therefore guarantees for $X_l = w_l v_l'$ that w_l is sufficiently different from λ^0 , and v_l is sufficiently different from f^0 .

Theorem 3.1 (Consistency). *Let Assumption 1, 2, 3, 4 be satisfied, let the parameter set \mathbb{B} be compact, and let $\beta^0 \in \mathbb{B}$. In the limit $N, T \rightarrow \infty$ we then have*

$$\widehat{\beta} \xrightarrow{p} \beta^0 .$$

We assume compactness of \mathbb{B} to guarantee existence of the minimizing $\widehat{\beta}$. We also use boundedness of \mathbb{B} in the consistency proof, but only for those parameters β_l , $l = 1 \dots K_1$, that correspond to low-rank regressors, i.e. if there are only high-rank regressors ($K_1 = 0$) the compactness assumption can be omitted, as long as existence of $\widehat{\beta}$ is guaranteed (e.g. for $\mathbb{B} = \mathbb{R}^K$).

Bai (2009) also proves consistency of the LS estimator of the interactive fixed effect model, but under somewhat different assumptions. He also employs, what we call Assumptions 1 and 2, and he uses a low-level version of Assumption 3. He demands the regressors to be strictly exogenous. Regarding consistency, the main difference between our assumptions and his is the treatment of high- and low-rank regressors. He first gives a condition on the regressors (his Assumption A) that rules out low-rank regressors, and later discussed the case where all regressors are either time-invariant or common regressors (*i.e.* are all low-rank). In contrast, our Assumption 4 allows for a combination of high- and low-rank regressors, and for low-rank regressors that are more general than time-invariant and common regressors.

4 Asymptotic Distribution and Bias Correction

Since we have already shown consistency of the LS estimator $\widehat{\beta}$, it is sufficient to study the local properties of the objective function $L_{NT}(\beta)$ around β^0 in order to derive the first order asymptotic theory of $\widehat{\beta}$. A useful approximation of $L_{NT}(\beta)$ around β^0 was derived in Moon and Weidner (2013), and we briefly summarize the ideas and results of this approximation in the following subsection. We then apply those results to derive the asymptotic distribution of the LS estimator, including working out the asymptotic bias, which was not done previously. Afterwards we discuss bias correction and inference.

4.1 Expansion of the Profile Objective Function

The last expression in equation (4) for the profile objective function is convenient because it does not involve any minimization over the parameters λ or f . On the other hand, this is not an expression that can be easily discussed by analytic means, because in general there is no explicit formula for the eigenvalues of a matrix. The conventional method that involves a Taylor series expansion in the regression parameters β *alone* seems infeasible here. In Moon and Weidner (2013) we showed how to overcome this problem by expanding the profile objective function *jointly* in β and $\|e\|$. The key idea is the following decomposition

$$Y - \beta \cdot X = \underbrace{\lambda^0 f^{0'}}_{\text{leading term}} - \underbrace{(\beta - \beta^0) \cdot X + e}_{\text{perturbation term}}.$$

If the perturbation term is zero, then the profile objective $L_{NT}(\beta)$ is also zero, since the leading term $\lambda^0 f^{0'}$ has rank R , so that the $T - R$ smallest eigenvalues of $f^0 \lambda^{0'} \lambda^0 f^{0'}$ all vanish. One may thus expect that small values of the perturbation term should correspond to small values of $L_{NT}(\beta)$. This idea can indeed be made mathematically precise. By using the perturbation theory of linear operators (see e.g. Kato (1980)) one can work out an expansion of $L_{NT}(\beta)$ in the perturbation term, and one can show that this expansion is convergent as long as the spectral norm of the perturbation term is sufficiently small.

The assumptions on the model made so far are in principle already sufficient to apply this expansion of the profile objective function, but in order to truncate the expansion at an appropriate order and to provide a bound on the remainder term which is sufficient to derive the first order asymptotic theory of the LS estimator, we need to strengthen Assumption 3 as follows.

Assumption 3*. $\|e\| = o_p(N^{2/3})$.

In the rest of the paper we only consider asymptotics where N and T grow at the same rate, i.e. we could equivalently write $o_p(T^{2/3})$ instead of $o_p(N^{2/3})$ in Assumption 3*. In Section S.2 of the supplementary material we provide examples of error distributions that satisfy Assumption 3*. In fact, for these examples, we have $\|e\| = \mathcal{O}_p(\sqrt{\max(N, T)})$. There is large literature that studies the asymptotic behavior of the spectral norm of random matrices, see e.g. Geman (1980), Silverstein (1989), Bai, Silverstein, Yin (1988), Yin, Bai, and Krishnaiah (1988), and Latala (2005). Loosely speaking, we expect the result $\|e\| = \mathcal{O}_p(\sqrt{\max(N, T)})$ to hold as long as the errors e_{it} have mean zero, uniformly bounded fourth moment, and weak time-serial and cross-sectional correlation (in some well-defined sense, see the examples).

We can now present the quadratic approximation of the profile objective function $L_{NT}(\beta)$ that was derived in Moon and Weidner (2013).

Theorem 4.1 (Expansion of Profile Objective Function). *Let Assumption 1, 3*, and 4(i) be satisfied, and consider the limit $N, T \rightarrow \infty$ with $N/T \rightarrow \kappa^2$, $0 < \kappa < \infty$. Then, the profile objective function satisfies $L_{NT}(\beta) = L_{q,NT}(\beta) + (NT)^{-1} R_{NT}(\beta)$, where the remainder $R_{NT}(\beta)$ is such that for any sequence $\eta_{NT} \rightarrow 0$ we have*

$$\sup_{\{\beta: \|\beta - \beta^0\| \leq \eta_{NT}\}} \frac{|R_{NT}(\beta)|}{\left(1 + \sqrt{NT} \|\beta - \beta^0\|\right)^2} = o_p(1),$$

and $L_{q,NT}(\beta)$ is a second order polynomial in β , namely

$$L_{q,NT}(\beta) = L_{NT}(\beta^0) - \frac{2}{\sqrt{NT}} (\beta - \beta^0)' C_{NT} + (\beta - \beta^0)' W_{NT} (\beta - \beta^0),$$

with $K \times K$ matrix W_{NT} defined by $W_{NT, k_1 k_2} = (NT)^{-1} \text{Tr}(M_{f^0} X'_{k_1} M_{\lambda^0} X_{k_2})$, and K -vector C_{NT} with entries $C_{NT, k} = C^{(1)}(\lambda^0, f^0, X_k, e) + C^{(2)}(\lambda^0, f^0, X_k, e)$, where

$$\begin{aligned} C^{(1)}(\lambda^0, f^0, X_k, e) &= \frac{1}{\sqrt{NT}} \text{Tr}(M_{f^0} e' M_{\lambda^0} X_k), \\ C^{(2)}(\lambda^0, f^0, X_k, e) &= -\frac{1}{\sqrt{NT}} \left[\text{Tr}(e M_{f^0} e' M_{\lambda^0} X_k f^0 (f^{0'} f^0)^{-1} (\lambda^{0'} \lambda^0)^{-1} \lambda^{0'}) \right. \\ &\quad + \text{Tr}(e' M_{\lambda^0} e M_{f^0} X'_k \lambda^0 (\lambda^{0'} \lambda^0)^{-1} (f^{0'} f^0)^{-1} f^{0'}) \\ &\quad \left. + \text{Tr}(e' M_{\lambda^0} X_k M_{f^0} e' \lambda^0 (\lambda^{0'} \lambda^0)^{-1} (f^{0'} f^0)^{-1} f^{0'}) \right]. \end{aligned}$$

We refer to W_{NT} and C_{NT} as the approximated Hessian and the approximated score (at the true parameter β^0). The exact Hessian and the exact score (at the true parameter β^0) contain higher order expansion terms in e , but the expansion up to the particular order above is sufficient to work out the first order asymptotic theory of the LS estimator, as the following corollary shows.

Corollary 4.2. *Let the assumptions of Theorem 3.1 and 4.1 hold, let β^0 be an interior point of the parameter set \mathbb{B} , and assume that $C_{NT} = \mathcal{O}_p(1)$. We then have $\sqrt{NT}(\widehat{\beta} - \beta^0) = W_{NT}^{-1}C_{NT} + o_p(1) = \mathcal{O}_p(1)$.*

Combining consistency of the LS estimator and the expansion of the profile objective function in Theorem 4.1, one obtains $\sqrt{NT}W_{NT}(\widehat{\beta} - \beta^0) = C_{NT} + o_p(1)$, see e.g. Andrews (1999). To obtain the corollary one needs in addition that W_{NT} does not become degenerate as $N, T \rightarrow \infty$, i.e. the smallest eigenvalue of W_{NT} should be bounded by a positive constant. Our assumptions already guarantee this, as is shown in the supplementary material.

4.2 Asymptotic Distribution

We now apply Corollary 4.2 to work out the asymptotic distribution of the LS estimator $\widehat{\beta}$. For this purpose we need more specific assumptions on λ^0 , f^0 , X_k , and e .

Assumption 5. *There exists a sigma algebra $\mathcal{C} = \mathcal{C}_{NT}$ (which in the following we will refer to as the conditioning set), which contains the sigma algebra generated by λ^0 and f^0 , such that*

- (i) $\mathbb{E}[e_{it} | \mathcal{C} \vee \sigma(\{(X_{is}, e_{i,s-1}), s \leq t\})] = 0$, for all i, t .¹²
- (ii) e_{it} is independent over t , conditional on \mathcal{C} , for all i .
- (iii) $\{(X_{it}, e_{it}), t = 1, \dots, T\}$ is independent across i , conditional on \mathcal{C} .
- (iv) $\frac{1}{NT} \sum_{i=1}^N \sum_{t,s=1}^T |\text{Cov}(X_{k,it}, X_{\ell,is} | \mathcal{C})| = \mathcal{O}_p(1)$, for all $k, \ell = 1, \dots, K$.
- (v) $\frac{1}{NT^2} \sum_{i=1}^N \sum_{t,s,u,v=1}^T |\text{Cov}(e_{it}\tilde{X}_{k,is}, e_{iu}\tilde{X}_{\ell,iv} | \mathcal{C})| = \mathcal{O}_p(1)$, where $\tilde{X}_{k,it} = X_{k,it} - \mathbb{E}[X_{k,it} | \mathcal{C}]$, for all $k, \ell = 1, \dots, K$.
- (vi) There exists an $\epsilon > 0$ such that $\mathbb{E}(e_{it}^8 | \mathcal{C})$ and $\mathbb{E}(\|X_{it}\|^{8+\epsilon} | \mathcal{C})$ and $\mathbb{E}\|\lambda_i^0\|^4$ and $\mathbb{E}\|f_t^0\|^{4+\epsilon}$ are bounded by a non-random constant, uniformly over i, t and N, T .
- (vii) β^0 is an interior point of the compact parameter set \mathbb{B} .

Remarks on Assumption 5

- (1) Part (i) of Assumption 5 imposes that e_{it} is a martingale difference sequence over time for a particular filtration. Conditioning on \mathcal{C} the time series of e_{it} is independent over time (part (ii) of the assumption) and the error term e_{it} and regressors X_{it} are cross-sectionally independent (part (iii) of the assumption), but unconditional correlation is

allowed. Part (iv) imposes weak time-serial correlation of X_{it} . Part (v) demands weak time-serial correlation of $\tilde{X}_{k,it} = X_{k,it} - \mathbb{E}[X_{k,it}|\mathcal{C}]$ and e_{it} . Finally, parts (vi) and (vii) require bounded higher moments of the error term, regressors, factors and factor loadings, a compact parameter set with interior true parameter.

- (2) Assumption 5(i) implies that $\mathbb{E}(X_{k,it}e_{it}|\mathcal{C}) = 0$ and $\mathbb{E}(X_{k,it}e_{it}X_{\ell,is}e_{is}|\mathcal{C}) = 0$ for $t \neq s$. Thus, the assumption guarantees that $X_{it}e_{it}$ is mean zero and uncorrelated over t , and independent across i , conditional on \mathcal{C} . Notice that the conditional mean independence restriction in Assumption 5(i) is weaker than Assumption D of Bai (2009), besides sequential exogeneity. Bai imposes independence between e_{it} and $(\{X_{js}, \lambda_j, f_s\}_{j,s})$.
- (3) Assumption 5 is sufficient for Assumption 2. To see this, notice that $\text{Tr}(X_k e') = \sum_{i,t} X_{k,it}e_{it}$, and that the sequential exogeneity and the cross-sectional independence assumption imply that $\mathbb{E}\left[\left((NT)^{-1} \sum_{i,t} X_{k,it}e_{it}\right)^2 \middle| \mathcal{C}\right] = (NT)^{-2} \sum_{i,t} \mathbb{E}\left[(X_{k,it}e_{it})^2 \middle| \mathcal{C}\right]$. Together with the assumption of bounded moments this gives $(NT)^{-1} \sum_{i,t} X_{k,it}e_{it} = o_p(1)$.
- (4) Assumption 5 is also sufficient for Assumption 3* (and thus for Assumption 3). This is because e_{it} is assumed independent over t and across i and has bounded 4'th moment, conditional on \mathcal{C} , which by using results in Latala (2005) implies that the spectral norm satisfies $\|e\| = \sqrt{\max(N, T)}$ as N and T become large, see the supplementary material.
- (5) Examples of regressor processes, which satisfy assumption Assumption 5(iv) and (v) are discussed in the following. This will also illuminate the role of the conditioning sigma field \mathcal{C} .

Examples of DGPs for X_{it}

Here we provide examples of the DGPs of the regressors X_{it} that satisfy the conditions in Assumption 5. Proofs for these examples are provided in the supplementary material.

Example 1. *The first example is a simple AR(1) interactive fixed effect regression*

$$Y_{it} = \beta^0 Y_{i,t-1} + \lambda_i^0 f_t^0 + e_{it},$$

where e_{it} is mean zero, independent across i and t , and independent of λ^0 and f^0 . Assume that $|\beta^0| < 1$ and that e_{it} , λ_i^0 and f_t^0 all possess uniformly bounded moments of order $8 + \epsilon$. In this case, the regressor is $X_{it} = Y_{it-1} = \lambda_i^0 F_t^0 + U_{it}$, where $F_t^0 = \sum_{s=0}^{\infty} (\beta^0)^s f_{t-1-s}^0$ and $U_{it} = \sum_{s=0}^{\infty} (\beta^0)^s e_{i,t-1-s}$. For the conditioning sigma field \mathcal{C} in Assumption 5, we choose $\mathcal{C} =$

$\sigma(\{\lambda_i^0 : 1 \leq i \leq N\}, \{f_t^0 : 1 \leq t \leq T\})$. Conditional on \mathcal{C} the only variation in X_{it} stems from U_{it} , which is independent across i and weakly correlated over t , so that Assumption 5(iv) holds. Furthermore, we have $\mathbb{E}(X_{it}|\mathcal{C}) = \lambda_i^{0'} F_t^0$ and $\tilde{X}_{it} = U_{it}$, which allows to verify Assumption 5(v).

This example can be generalized to a VAR(1) model as follows:

$$\begin{pmatrix} Y_{it} \\ Z_{it} \end{pmatrix} = \mathcal{B} \underbrace{\begin{pmatrix} Y_{i,t-1} \\ Z_{i,t-1} \end{pmatrix}}_{=X_{it}} + \begin{pmatrix} \lambda_i^{0'} f_t^0 \\ d_{it} \end{pmatrix} + \underbrace{\begin{pmatrix} e_{it} \\ u_{it} \end{pmatrix}}_{=E_{it}}, \quad (5)$$

where Z_{it} is an $m \times 1$ vector of additional variables and \mathcal{B} is an $(m+1) \times (m+1)$ matrix of VAR parameters whose eigenvalues lie within the unit circle. The $m \times 1$ vector d_{it} and the factors f_t^0 and factor loadings λ_i^0 are assumed to be independent of the $(m+1) \times 1$ vector of innovations E_{it} . Suppose that our interest is to estimate the first row in equation (5), which corresponds exactly to our interactive fixed effects model with regressors $Y_{i,t-1}$ and $Z_{i,t-1}$. Choosing \mathcal{C} to be the sigma field generated by all f_t^0 , λ_i^0 , d_{it} we obtain $\tilde{X}_{it} = \sum_{s=0}^{\infty} \mathcal{B}^s E_{i,t-1-s}$. Analogous to the AR(1) case we then find that Assumption 5(iv) and (v) are satisfied in this example if the innovations E_{it} are independent across i and over t , have appropriate bounded moments.

Example 2. Consider a scalar X_{it} for simplicity, and let $X_{it} = g(v_{it}, \delta_i, h_t)$. We assume that (i) $\{(e_{it}, v_{it})_{i=1, \dots, N; t=1, \dots, T}\} \perp \{(\lambda_i^0, \delta_i)_{i=1, \dots, N}, (f_t^0, h_t)_{t=1, \dots, T}\}$, (ii) $(e_{it}, v_{it}, \delta_i)$ are independent across i for all t , and (iii) $v_{is} \perp e_{it}$ for $s \leq t$ and all i . Furthermore assume that $\sup_{it} \mathbb{E}|X_{it}|^{8+\epsilon} < \infty$ for some positive ϵ . For the conditioning sigma field \mathcal{C} in Assumption 5 we choose $\mathcal{C} = \sigma(\{\lambda_i^0 : 1 \leq i \leq N\}, \{\delta_i : 1 \leq i \leq N\}, \{f_t^0 : -\infty \leq t \leq \infty\}, \{h_t : -\infty \leq t \leq \infty\})$. Furthermore, let $\mathcal{F}_\tau^t(i) = \mathcal{C} \vee \sigma(\{(e_{is}, v_{is}) : \tau \leq s \leq t\})$, and define the conditional α -mixing coefficient on \mathcal{C} ,

$$\alpha_m(i) = \sup_{A \in \mathcal{F}_{-\infty}^t(i), B \in \mathcal{F}_{t+m}^\infty(i)} [\mathbb{P}(A \cap B) - \mathbb{P}(A)\mathbb{P}(B) | \mathcal{C}].$$

Let $\alpha_m = \sup_i \alpha_m(i)$, and assume that $\alpha_m = O(m^{-\zeta})$, where $\zeta > \frac{12p}{4p-1}$ for $p > 4$. Then, Assumption 5(iv) and (v) are satisfied.

In this example, the shocks h_t (which may contain the factors f_t^0), δ_i (which may contain the factor loadings λ_i^0), and v_{it} (which may contain past values of e_{it}) can enter in a general non-linear way into the regressor X_{it} .

The following assumption guarantees that the limiting variance and the asymptotic bias converge to constant values.

Assumption 6. Let $\mathcal{X}_k = M_{\lambda^0} X_k M_{f^0}$, which is an $N \times T$ matrix with entries $\mathcal{X}_{k,it}$. For each i and t , define the K -vector $\mathcal{X}_{it} = (\mathcal{X}_{1,it}, \dots, \mathcal{X}_{K,it})'$. We assume existence of the following

probability limits for all $k = 1, \dots, K$,

$$\begin{aligned}
 W &= \text{plim}_{N,T \rightarrow \infty} \frac{1}{NT} \sum_{i=1}^N \sum_{t=1}^T \mathcal{X}_{it} \mathcal{X}'_{it}, \\
 \Omega &= \text{plim}_{N,T \rightarrow \infty} \frac{1}{NT} \sum_{i=1}^N \sum_{t=1}^T e_{it}^2 \mathcal{X}_{it} \mathcal{X}'_{it}, \\
 B_{1,k} &= \text{plim}_{N,T \rightarrow \infty} \frac{1}{N} \text{Tr} [P_{f^0} \mathbb{E} (e' X_k | \mathcal{C})], \\
 B_{2,k} &= \text{plim}_{N,T \rightarrow \infty} \frac{1}{T} \text{Tr} [\mathbb{E} (ee' | \mathcal{C}) M_{\lambda^0} X_k f^0 (f^{0'} f^0)^{-1} (\lambda^{0'} \lambda^0)^{-1} \lambda^{0'}], \\
 B_{3,k} &= \text{plim}_{N,T \rightarrow \infty} \frac{1}{N} \text{Tr} [\mathbb{E} (e'e | \mathcal{C}) M_{f^0} X'_k \lambda^0 (\lambda^{0'} \lambda^0)^{-1} (f^{0'} f^0)^{-1} f^{0'}],
 \end{aligned}$$

where \mathcal{C} is the same conditioning set that appears in Assumption 5.

Here, W and Ω are $K \times K$ matrices, and we define the K -vectors B_1 , B_2 and B_3 with components $B_{1,k}$, $B_{2,k}$ and $B_{3,k}$, $k = 1, \dots, K$.

Theorem 4.3 (Asymptotic Distribution). *Let Assumptions 1, 4, 5 and 6 be satisfied,¹³ and consider the limit $N, T \rightarrow \infty$ with $N/T \rightarrow \kappa^2$, where $0 < \kappa < \infty$. Then we have*

$$\sqrt{NT} \left(\widehat{\beta} - \beta^0 \right) \xrightarrow{d} \mathcal{N} \left(W^{-1} B, W^{-1} \Omega W^{-1} \right),$$

where $B = -\kappa B_1 - \kappa^{-1} B_2 - \kappa B_3$.

From Corollary 4.2 we already know that the limiting distribution of $\widehat{\beta}$ is given by the limiting distribution of $W_{NT}^{-1} C_{NT}$. Note that $W_{NT} = \frac{1}{NT} \sum_{i=1}^N \sum_{t=1}^T \mathcal{X}_{it} \mathcal{X}'_{it}$, i.e. W is simply defined as the probability limit of W_{NT} . Assumption 4 guarantees that W is positive definite, as shown in the supplementary material.

Thus, the main task in proving Theorem 4.3 is to show that the approximated score at the true parameter satisfies $C_{NT} \rightarrow_d \mathcal{N}(B, \Omega)$. It turns out that the asymptotic variance Ω and the asymptotic bias B_1 originate from the $C^{(1)}$ term, while the two further bias terms B_2 and B_3 originate from the $C^{(2)}$ term of C_{NT} .

The bias B_1 is due to correlation of the errors e_{it} and the regressors $X_{k,i\tau}$ in the time direction (for $\tau > t$). This bias term generalizes the Nickell (1981) bias that occurs in dynamic models with standard fixed effects, and it is not present in Bai (2009), where only strictly exogenous regressors are considered.

The other two bias terms B_2 and B_3 are already described in Bai (2009). If e_{it} is homoscedastic, i.e. if $\mathbb{E}(e_{it} | \mathcal{C}) = \sigma^2$, then $\mathbb{E}(ee' | \mathcal{C}) = \sigma^2 \mathbb{I}_N$ and $\mathbb{E}(e'e | \mathcal{C}) = \sigma^2 \mathbb{I}_T$, so that $B_2 = 0$ and $B_3 = 0$

(because the trace is cyclical and $f^0 M_{f^0} = 0$ and $\lambda^0 M_{\lambda^0} = 0$). Thus, B_2 is only non-zero if e_{it} is heteroscedastic across i , and B_3 is only non-zero if e_{it} is heteroscedastic over t . Correlation in e_{it} across i or over t would also generate non-zero bias terms of exactly the form B_2 and B_3 , but is ruled out by our assumptions.

4.3 Bias Correction

Estimators for W , Ω , B_1 , B_2 , and B_3 are obtained by forming suitable sample analogs and replacing the unobserved λ^0 , f^0 and e by the estimates $\hat{\lambda}$, \hat{f} and the residuals \hat{e} .

Definition 1. Let $\hat{\mathcal{X}}_k = M_{\hat{\lambda}} X_k M_{\hat{f}}$. For each i and t , define the K -vector $\hat{\mathcal{X}}_{it} = (\hat{\mathcal{X}}_{1,it}, \dots, \hat{\mathcal{X}}_{K,it})'$. Let $\Gamma : \mathbb{R} \rightarrow \mathbb{R}$ be the truncation kernel defined by $\Gamma(x) = 1$ for $|x| \leq 1$, and $\Gamma(x) = 0$ otherwise. Let M be a bandwidth parameter that depends on N and T . We define the $K \times K$ matrices \widehat{W} and $\widehat{\Omega}$, and the K -vectors \widehat{B}_1 , \widehat{B}_2 and \widehat{B}_3 as follows

$$\begin{aligned}\widehat{W} &= \frac{1}{NT} \sum_{i=1}^N \sum_{t=1}^T \hat{\mathcal{X}}_{it} \hat{\mathcal{X}}'_{it}, \\ \widehat{\Omega} &= \frac{1}{NT} \sum_{i=1}^N \sum_{t=1}^T (\hat{e}_{it})^2 \hat{\mathcal{X}}_{it} \hat{\mathcal{X}}'_{it}, \\ \widehat{B}_{1,k} &= \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^{T-1} \sum_{s=t+1}^T \Gamma\left(\frac{s-t}{M}\right) [P_{\hat{f}}]_{ts} \hat{e}_{it} X_{k,is}, \\ \widehat{B}_{2,k} &= \frac{1}{T} \sum_{i=1}^N \sum_{t=1}^T (\hat{e}_{it})^2 \left[M_{\hat{\lambda}} X_k \hat{f} (\hat{f}' \hat{f})^{-1} (\hat{\lambda}' \hat{\lambda})^{-1} \hat{\lambda}' \right]_{ii}, \\ \widehat{B}_{3,k} &= \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T (\hat{e}_{it})^2 \left[M_{\hat{f}} X'_k \hat{\lambda} (\hat{\lambda}' \hat{\lambda})^{-1} (\hat{f}' \hat{f})^{-1} \hat{f}' \right]_{tt},\end{aligned}$$

where $\hat{e} = Y - \hat{\beta} \cdot X - \hat{\lambda} \hat{f}'$, and \hat{e}_{it} denotes the elements of \hat{e} , $[A]_{ts}$ denotes the (t,s) 'th element of the matrix A .

Notice that the estimators $\widehat{\Omega}$, \widehat{B}_2 , and \widehat{B}_3 are similar to White's standard error estimator under heteroskedasticity and the estimator \widehat{B}_1 is similar to the HAC estimator with a kernel.

To show consistency of these estimators we impose some additional assumptions.

Assumption 7.

(i) $\|\lambda_i^0\|$ and $\|f_t^0\|$ are uniformly bounded over i, t and N, T .

(ii) There exists $c > 0$ and $\epsilon > 0$ such that for all i, t, m, N, T we have

$$\left| \frac{1}{N} \sum_{i=1}^N \mathbb{E}(e_{it} X_{k,it+m} \mid \mathcal{C}) \right| \leq c m^{-(1+\epsilon)}.$$

Assumption 7(i) is made for convenience in order to simplify the consistency proof for the estimators in Definition 1. It is possible to weaken this assumption by only assuming suitable bounded moments of $\|\lambda_i^0\|$ and $\|f_t^0\|$. In order to show consistency of \widehat{B}_1 we need to control how strongly e_{it} and $X_{k,it}$, $t < \tau$, are allowed to be correlated, which is done by Assumption 7(ii). It is straightforward to verify that Assumption 7(ii) is satisfied in the two examples of regressors processes presented after Assumption 5.

Theorem 4.4 (Consistency of Bias and Variance Estimators). *Let Assumptions 1, 4, 5, 6 and 7 hold, and consider a limit $N, T \rightarrow \infty$ with $N/T \rightarrow \kappa^2$, $0 < \kappa < \infty$, such that the bandwidth $M = M_{NT}$ satisfies $M \rightarrow \infty$ and $M^5/T \rightarrow 0$. We then have $\widehat{W} = W + o_p(1)$, $\widehat{\Omega} = \Omega + o_p(1)$, $\widehat{B}_1 = B_1 + o_p(1)$, $\widehat{B}_2 = B_2 + o_p(1)$, and $\widehat{B}_3 = B_3 + o_p(1)$.*

The assumption $M^5/T \rightarrow 0$ can be relaxed if additional higher moment restrictions on e_{it} and $X_{k,it}$ are imposed. Note also that for the construction of the estimators \widehat{W} , $\widehat{\Omega}$, and \widehat{B}_i , $i = 1, 2, 3$, it is not necessary to know whether the regressors are strictly exogenous or predetermined; in both cases the estimators for W , Ω , and B_i , $i = 1, 2, 3$, are consistent. We can now present our bias corrected estimator and its limiting distribution.

Corollary 4.5. *Under the assumptions of Theorem 4.4 the bias corrected estimator*

$$\widehat{\beta}^* = \widehat{\beta} + \widehat{W}^{-1} \left(T^{-1} \widehat{B}_1 + N^{-1} \widehat{B}_2 + T^{-1} \widehat{B}_3 \right)$$

satisfies $\sqrt{NT} \left(\widehat{\beta}^ - \beta^0 \right) \rightarrow_d \mathcal{N} \left(0, W^{-1} \Omega W^{-1} \right)$.*

According to Theorem 4.4, a consistent estimator of the asymptotic variance of $\widehat{\beta}^*$ is given by $\widehat{W}^{-1} \widehat{\Omega} \widehat{W}^{-1}$.

An alternative to the analytical bias correction result given by Corollary 4.5 is to use Jackknife bias correction in order to eliminate the asymptotic bias. For panel models with incidental parameters only in the cross-sectional dimensions one typically finds a large N, T leading incidental parameter bias of order $1/T$ for the parameters of interest. To correct for this $1/T$ bias

one can use the delete-one Jackknife bias correction if observations are iid over t (Hahn and Newey, 2004) and the split-panel Jackknife bias correction if observations are correlated over t (Dhaene and Jochmans, 2010). In our current model we have incidental parameters in both panel dimensions (λ_i^0 and f_t^0), resulting in leading bias terms of order $1/T$ (bias term B_1 and B_3) and of order $1/N$ (bias term B_2). The generalizations of the split-panel Jackknife bias correction to that case was discussed in Fernández-Val and Weidner (2013).

The corresponding bias corrected split-panel Jackknife estimator reads $\widehat{\beta}^J = 3\widehat{\beta}_{NT} - \overline{\beta}_{N,T/2} - \overline{\beta}_{N/2,T}$, where $\widehat{\beta}_{NT} = \widehat{\beta}$ is the LS estimator obtained from the full sample, $\overline{\beta}_{N,T/2}$ is the average of the two LS estimators that leave out the first and second halves of the time periods, and $\overline{\beta}_{N/2,T}$ is the average of the two LS estimators that leave out half of the individuals. Jackknife bias correction is convenient since only the order of the bias, but not the structure of the terms B_1 , B_2 , B_3 needs not be known in detail. However, one requires additional stationarity assumptions over t and homogeneity assumptions across i in order to justify the Jackknife correction and to show that $\widehat{\beta}^J$ has the same limiting distribution as $\widehat{\beta}^*$ in Corollary 4.5, see Fernández-Val and Weidner (2013) for more details. They also observe through Monte Carlo simulations that the finite sample variance of the Jackknife corrected estimator is often larger than of the analytically corrected estimator. Jackknife bias correction is not explored further in this paper.

5 Testing Restrictions on β^0

In this section we discuss the three classical test statistics for testing linear restrictions on β^0 . The null-hypothesis is $H_0 : H\beta^0 = h$, and the alternative is $H_a : H\beta^0 \neq h$, where H is an $r \times K$ matrix of rank $r \leq K$, and h is an $r \times 1$ vector. We restrict the presentation to testing a linear hypothesis for ease of exposition. One can generalize the discussion to the testing of non-linear hypotheses, under conventional regularity conditions. Throughout this subsection we assume that β^0 is an interior point of \mathbb{B} , i.e. there are no local restrictions on β as long as the null-hypothesis is not imposed. Using the expansion of $L_{NT}(\beta)$ one could also discuss testing when the true parameter is on the boundary, as shown in Andrews (2001).

The restricted estimator is defined by

$$\widetilde{\beta} = \underset{\beta \in \widetilde{\mathbb{B}}}{\operatorname{argmin}} L_{NT}(\beta) , \tag{6}$$

where $\widetilde{\mathbb{B}} = \{\beta \in \mathbb{B} | H\beta = h\}$ is the restricted parameter set. Analogous to Theorem 4.3 for the unrestricted estimator $\widehat{\beta}$, we can use the expansion of the profile objective function to derive the limiting distribution of the restricted estimator. Under the assumptions of Theorem 4.3 we

have

$$\sqrt{NT}(\tilde{\beta} - \beta^0) \xrightarrow{d} \mathcal{N}(\mathfrak{W}^{-1}B, \mathfrak{W}^{-1}\Omega\mathfrak{W}^{-1}),$$

where $\mathfrak{W}^{-1} = W^{-1} - W^{-1}H'(HW^{-1}H')^{-1}HW^{-1}$. The $K \times K$ covariance matrix in the limiting distribution of $\tilde{\beta}$ is not full rank, but satisfies $\text{rank}(\mathfrak{W}^{-1}\Omega\mathfrak{W}^{-1}) = K - r$, because $H\mathfrak{W}^{-1} = 0$ and thus $\text{rank}(\mathfrak{W}^{-1}) = K - r$. The asymptotic distribution of $\sqrt{NT}(\tilde{\beta} - \beta^0)$ is therefore $K - r$ dimensional, as it should be for the restricted estimator.

Wald Test

Using the result of Theorem 4.3 we find that under the null-hypothesis $\sqrt{NT}(H\hat{\beta} - h)$ is asymptotically distributed as $\mathcal{N}(HW^{-1}B, HW^{-1}\Omega W^{-1}H')$. Thus, due to the presence of the bias B , the standard Wald test statistics $WD_{NT} = NT(H\hat{\beta} - h)'(H\widehat{W}^{-1}\widehat{\Omega}\widehat{W}^{-1}H')^{-1}(H\hat{\beta} - h)$ is not asymptotically χ_r^2 distributed. Using the estimator $\widehat{B} = -\sqrt{\frac{N}{T}}\widehat{B}_1 - \sqrt{\frac{T}{N}}\widehat{B}_2 - \sqrt{\frac{N}{T}}\widehat{B}_3$ for the bias we can define the bias corrected Wald test statistics as

$$WD_{NT}^* = \left[\sqrt{NT}(H\widehat{\beta}^* - h) \right]' (H\widehat{W}^{-1}\widehat{\Omega}\widehat{W}^{-1}H')^{-1} \left[\sqrt{NT}(H\widehat{\beta}^* - h) \right], \quad (7)$$

where $\widehat{\beta}^* = \widehat{\beta} - \widehat{W}^{-1}\widehat{B}$ is the bias corrected estimator. This is just the standard Wald test statistics applied to $\widehat{\beta}^*$. Under the null hypothesis and the Assumptions of Theorem 4.4 we find $WD_{NT}^* \xrightarrow{d} \chi_r^2$.

Likelihood Ratio Test

To implement the LR test we need the relationship between the asymptotic Hessian W and the asymptotic score variance Ω of the profile objective function to be of the form $\Omega = cW$, where $c > 0$ is a scalar constant. This is satisfied in our interactive fixed effect model if $\mathbb{E}(e_{it}^2|\mathcal{C}) = c$, i.e. if the error is homoskedastic. A consistent estimator for c is then given by $\widehat{c} = (NT)^{-1} \sum_{i=1}^N \sum_{t=1}^T \widehat{e}_{it}^2$, where $\widehat{e} = Y - \widehat{\beta} \cdot X - \widehat{\lambda} \widehat{f}'$. Since the likelihood function for the interactive fixed effect model is just the sum of squared residuals, we have $\widehat{c} = L_{NT}(\widehat{\beta})$. The likelihood ratio test statistics is defined by

$$LR_{NT} = \widehat{c}^{-1} NT \left[L_{NT}(\tilde{\beta}) - L_{NT}(\widehat{\beta}) \right].$$

Under the assumption of Theorem 4.3 we then have

$$LR_{NT} \xrightarrow{d} c^{-1} C'W^{-1}H'(HW^{-1}H')^{-1}HW^{-1}C,$$

where $C \sim \mathcal{N}(B, \Omega)$, i.e. $C_{NT} \rightarrow_d C$. This is the same limiting distribution that one finds for the Wald test if $\Omega = cW$ (in fact, one can show $WD_{NT} = LR_{NT} + o_p(1)$). Therefore, we need to do a bias correction for the LR test in order to achieve a χ^2 limiting distribution. We define

$$LR_{NT}^* = \widehat{c}^{-1} NT \left[\min_{\{\beta \in \mathbb{B} \mid H\beta = h\}} L_{NT} \left(\beta + (NT)^{-1/2} \widehat{W}^{-1} \widehat{B} \right) - \min_{\beta \in \mathbb{B}} L_{NT} \left(\beta + (NT)^{-1/2} \widehat{W}^{-1} \widehat{B} \right) \right], \quad (8)$$

where \widehat{B} and \widehat{W} do not depend on the parameter β in the minimization problem.¹⁴ Asymptotically we have $\min_{\beta \in \mathbb{B}} L_{NT} \left(\beta + (NT)^{-1/2} \widehat{W}^{-1} \widehat{B} \right) = L_{NT}(\widehat{\beta})$, because $\beta \in \mathbb{B}$ does not impose local constraints, i.e. close to β^0 it does not matter for the value of the minimum whether one minimizes over β or over $\beta + (NT)^{-1/2} \widehat{W}^{-1} \widehat{B}$. The correction to the LR test therefore originates from the first term in LR_{NT}^* . For the minimization over the restricted parameter set it matters whether the argument of L_{NT} is β or $\beta + (NT)^{-1/2} \widehat{W}^{-1} \widehat{B}$, because generically we have $HW^{-1}B \neq 0$ (otherwise no correction would be necessary for the LR statistics). One can show that

$$LR_{NT}^* \xrightarrow{d} c^{-1} (C - B)' W^{-1} H' (HW^{-1} H')^{-1} HW^{-1} (C - B),$$

i.e. we obtain the same formula as for LR_{NT} , but the limit of the score C is replaced by the bias corrected term $C - B$. Under the Assumptions of Theorem 4.4, if H_0 is satisfied, and for homoscedastic errors e_{it} , we have $LR_{NT}^* \rightarrow_d \chi_r^2$. In fact, one can show that $LR_{NT}^* = WD_{NT}^* + o_p(1)$.

Lagrange Multiplier Test

Let $\widetilde{\nabla} \mathcal{L}_{NT}$ be the gradient of the LS objective function (2) with respect to β , evaluated at the restricted parameter estimates, i.e.

$$\begin{aligned} \widetilde{\nabla} \mathcal{L}_{NT} &= \nabla \mathcal{L}_{NT}(\widetilde{\beta}, \widetilde{\lambda}, \widetilde{f}) = \left(\frac{\partial \mathcal{L}_{NT}(\beta, \widetilde{\lambda}, \widetilde{f})}{\partial \beta_1} \Big|_{\beta=\widetilde{\beta}}, \dots, \frac{\partial \mathcal{L}_{NT}(\beta, \widetilde{\lambda}, \widetilde{f})}{\partial \beta_K} \Big|_{\beta=\widetilde{\beta}} \right)' \\ &= -\frac{2}{NT} \left(\text{Tr}(X'_1 \widetilde{e}), \dots, \text{Tr}(X'_K \widetilde{e}) \right)', \end{aligned}$$

where $\widetilde{\lambda} = \widehat{\lambda}(\widetilde{\beta})$, $\widetilde{f} = \widehat{f}(\widetilde{\beta})$, and $\widetilde{e} = Y - \widetilde{\beta} \cdot X - \widetilde{\lambda} \widetilde{f}'$. Under the Assumptions of Theorem 4.3, and if the null hypothesis $H_0 : H\beta^0 = h$ is satisfied, one finds that¹⁵

$$\sqrt{NT} \widetilde{\nabla} \mathcal{L}_{NT} = \sqrt{NT} \nabla L_{NT}(\widetilde{\beta}) + o_p(1). \quad (9)$$

Due to this equation, one can base the Lagrange multiplier test on the gradient of $\mathcal{L}_{NT}(\tilde{\beta}, \tilde{\lambda}, \tilde{f})$, or on the gradient of the profile quasi-likelihood function $L_{NT}(\tilde{\beta})$ and obtains the same limiting distribution.

Using the bound on the remainder $R_{NT}(\beta)$ given in Theorem 4.1, one cannot infer any properties of the score function, i.e. of the gradient $\nabla L_{NT}(\beta)$, because nothing is said about $\nabla R_{NT}(\beta)$. The following theorem gives the bound on $\nabla R_{NT}(\beta)$ that is sufficient to derive the limiting distribution of the Lagrange multiplier.

Theorem 5.1. *Under the assumptions of Theorem 4.1, and with W_{NT} and C_{NT} as defined there, the score function satisfies*

$$\nabla L_{NT}(\beta) = 2W_{NT}(\beta - \beta^0) - \frac{2}{\sqrt{NT}}C_{NT} + \frac{1}{NT}\nabla R_{NT}(\beta),$$

where the remainder $\nabla R_{NT}(\beta)$ satisfies for any sequence $\eta_{NT} \rightarrow 0$

$$\sup_{\{\beta: \|\beta - \beta^0\| \leq \eta_{NT}\}} \frac{\|\nabla R_{NT}(\beta)\|}{\sqrt{NT} \left(1 + \sqrt{NT} \|\beta - \beta^0\|\right)} = o_p(1).$$

From this theorem, and the fact that $\tilde{\beta}$ is \sqrt{NT} -consistent under H_0 , we obtain

$$\begin{aligned} \sqrt{NT} \tilde{\nabla} \mathcal{L}_{NT} &= \sqrt{NT} \nabla L_{q,NT}(\tilde{\beta}) + o_p(1) \\ &= 2\sqrt{NT}W_{NT}(\tilde{\beta} - \beta^0) - 2C_{NT} + o_p(1). \end{aligned}$$

Remember that $\tilde{\beta}$ is the restricted estimator defined in equation (6). Using this result and the known limiting distribution of $\tilde{\beta}$ we now find

$$\sqrt{NT} \tilde{\nabla} \mathcal{L}_{NT} \xrightarrow{d} -2H'(HW^{-1}H')^{-1}HW^{-1}C. \quad (10)$$

Note also that $\sqrt{NT}HW^{-1}\nabla L_{NT}(\tilde{\beta}) \xrightarrow{d} -2HW^{-1}C$. We define \tilde{B} , \tilde{W} and $\tilde{\Omega}$ analogous to \hat{B} , \hat{W} and $\hat{\Omega}$, but with unrestricted parameter estimates replaced by restricted parameter estimates. The LM test statistics is then given by

$$LM_{NT} = \frac{NT}{4} (\tilde{\nabla} \mathcal{L}_{NT})' \tilde{W}^{-1} H' (H \tilde{W}^{-1} \tilde{\Omega} \tilde{W}^{-1} H')^{-1} H \tilde{W}^{-1} \tilde{\nabla} \mathcal{L}_{NT}.$$

One can show that the LM test is asymptotically equivalent to the Wald test: $LM_{NT} = WD_{NT} + o_p(1)$, i.e. again bias correction is necessary. We define the bias corrected LM test statistics as

$$LM_{NT}^* = \frac{1}{4} \left(\sqrt{NT} \tilde{\nabla} \mathcal{L}_{NT} + 2\tilde{B} \right)' \tilde{W}^{-1} H' (H \tilde{W}^{-1} \tilde{\Omega} \tilde{W}^{-1} H')^{-1} H \tilde{W}^{-1} \left(\sqrt{NT} \tilde{\nabla} \mathcal{L}_{NT} + 2\tilde{B} \right). \quad (11)$$

The following theorem summarizes the main results of the present subsection.

Theorem 5.2 (Chi-Square Limit of Bias Corrected Test Statistics). *Let the assumptions of Theorem 4.4 and the null hypothesis $H_0 : H\beta^0 = h$ be satisfied. For the bias corrected Wald and LM test statistics introduced in equation (7) and (11) we then have*

$$WD_{NT}^* \xrightarrow{d} \chi_r^2, \quad LM_{NT}^* \xrightarrow{d} \chi_r^2.$$

If in addition we assume $\mathbb{E}(e_{it}^2|\mathcal{C}) = c$, i.e. the idiosyncratic errors are homoscedastic, and we use $\hat{c} = L_{NT}(\hat{\beta})$ as an estimator for c , then the LR test statistics defined in equation (8) satisfies

$$LR_{NT}^* \xrightarrow{d} \chi_r^2.$$

6 Extension to Endogenous Regressors

In this section we briefly discuss how to estimate the regression coefficient β^0 of Model (1) when some of the regressors in X_{it} are endogenous with respect to the regression error e_{it} . The question is how instrumental variables can be used to estimate the regression coefficients of the endogenous regressor in the presence of the interactive fixed effects $\lambda_i^{0'} f_t^0$.

In the existing literature similar questions were already investigated under various setups. Harding and Lamarche (2009; 2011) investigate the problem of estimating an endogenous panel (quantile) regression with interactive fixed effects and show how to use IVs in the CCE estimation framework. Moon, Shum and Weidner (2012) (hereafter MSW) estimate a random coefficient multinomial demand model (as in Berry, Levinsohn and Pakes (1995))) when the unobserved product-market characteristics have interactive fixed effects. The IVs are required to identify the parameters of the random coefficient distribution and to control for price endogeneity. They suggested a multi-step “least squares-minimum distance” (LS-MD) estimator.¹⁶ The LS-MD approach is also applicable to linear panel regression models with endogenous regressors and interactive fixed effects, as demonstrated in Lee, Moon, and Weidner (2012) for the case of a dynamic linear panel regression model with interactive fixed effects and measurement error.

We now discuss how to implement the LS-MD estimation in our setup. Let X_{it}^{end} be the vectors of endogenous regressors, and let X_{it}^{exo} be the vector of exogenous regressors, with respect to e_{it} , such that $X_{it} = (X_{it}^{\text{end}'}, X_{it}^{\text{exo}'})'$. The model then reads

$$Y_{it} = \beta_{\text{end}}^{0'} X_{it}^{\text{end}} + \beta_{\text{exo}}^{0'} X_{it}^{\text{exo}} + \lambda_i^{0'} f_t^0 + e_{it},$$

where X_{it}^{exo} denotes the exogenous and X_{it}^{end} denotes the endogenous regressors (wrt to e_{it}). Suppose that Z_{it} is an additional L -vector of exogenous instrumental variables (IVs), but Z_{it}

may be correlated with λ_i^0 and f_t^0 . The LS-MD estimator of $\beta^0 = (\beta_{\text{end}}^{0'}, \beta_{\text{exo}}^{0'})'$ can then be calculated by the following three steps:

- (1) For given β_{end} we run the least squares regression of $Y_{it} - \beta_{\text{end}}' X_{it}^{\text{end}}$ on the included exogenous regressors X_{it}^{exo} , the interactive fixed effects $\lambda_i' f_t$, and the IVs Z_{it} :

$$\begin{aligned} & \left(\tilde{\beta}_{\text{exo}}(\beta_{\text{end}}), \tilde{\gamma}(\beta_{\text{end}}), \tilde{\lambda}(\beta_{\text{end}}), \tilde{f}(\beta_{\text{end}}) \right) \\ &= \underset{\{\beta_{\text{exo}}, \gamma, \lambda, f\}}{\text{argmin}} \sum_{i=1}^N \sum_{t=1}^T \left(Y_{it} - \beta_{\text{end}}' X_{it}^{\text{end}} - \beta_{\text{exo}}' X_{it}^{\text{exo}} - \gamma' Z_{it} - \lambda_i' f_t \right)^2. \end{aligned}$$

- (2) We estimate β_{end} by finding $\tilde{\gamma}(\beta_{\text{end}})$, obtained by step (1), that is closest to zero. For this, we choose a symmetric positive definite $L \times L$ weight matrix W_{NT}^γ and compute

$$\hat{\beta}_{\text{end}} = \underset{\beta_{\text{end}}}{\text{argmin}} \tilde{\gamma}(\beta_{\text{end}})' W_{NT}^\gamma \tilde{\gamma}(\beta_{\text{end}}).$$

- (3) We estimate β_{exo} (and λ, f) by running the least squares regression of $Y_{it} - \hat{\beta}_{\text{end}}' X_{it}^{\text{end}}$ on the included exogenous regressors X_{it}^{exo} and the interactive fixed effects $\lambda_i' f_t$:

$$\left(\hat{\beta}_{\text{exo}}, \hat{\lambda}, \hat{f} \right) = \underset{\{\beta_{\text{exo}}, \gamma, \lambda, f\}}{\text{argmin}} \sum_{i=1}^N \sum_{t=1}^T \left(Y_{it} - \hat{\beta}_{\text{end}}' X_{it}^{\text{end}} - \beta_{\text{exo}}' X_{it}^{\text{exo}} - \lambda_i' f_t \right)^2.$$

The idea behind this estimation procedure is that valid instruments are excluded from the model for Y_{it} , so that their first step regression coefficients $\tilde{\gamma}(\beta_{\text{end}})$ should be close to zero if β_{end} is close to its true value β_{end}^0 . Thus, as long as X_{it}^{exo} and Z_{it} jointly satisfy the assumptions of the current paper we obtain $\tilde{\gamma}(\beta_{\text{end}}^0) = o_p(1)$ for the first step LS estimator, and we also obtain the asymptotic distribution of $\tilde{\gamma}(\beta_{\text{end}}^0)$ from the results derived in Section 4.

However, to justify the second step minimization formally one needs to study the properties of $\tilde{\gamma}(\beta_{\text{end}})$ also for $\beta_{\text{end}} \neq \beta_{\text{end}}^0$. For this we refer to MSW. Our $\beta_{\text{end}}, \beta_{\text{exo}}$, and $Y_{it} - \beta_{\text{end}}' X_{it}^{\text{end}}$ correspond to their α, β and $\delta_{jt}(\alpha)$, respectively. The Assumptions 1 to 5 in MSW can be translated accordingly, and the results in MSW show large N, T consistency and asymptotic normality of the LS-MD estimator.

The final step of the LS-MD estimation procedure is essentially a repetition of the first step, but without including Z_{it} in the set of regressors, which results in some efficiency gains for $\hat{\beta}_{\text{exo}}$ compared to the first step.

7 Monte Carlo Simulations

We consider an AR(1) model with $R = 1$ factors:

$$Y_{it} = \rho^0 Y_{i,t-1} + \lambda_i^0 f_t^0 + e_{it}.$$

We estimate the model as an interactive fixed effect model, i.e. no distributional assumption on λ_i^0 and f_t^0 are made in the estimation. The parameter of interest is ρ^0 . The estimators we consider are the OLS estimator (which completely ignores the presence of the factors), the least squares estimator with interactive fixed effects (denoted FLS in this section to differentiate from OLS) defined in equation (3),¹⁷ and its bias corrected version (denoted BC-FLS), defined in Theorem 4.5.

For the simulation we draw the e_{it} independently and identically distributed from a t -distribution with five degrees of freedom, the λ_i^0 independently distributed from $\mathcal{N}(1, 1)$, and we generate the factors from an AR(1) specification, namely $f_t^0 = \rho_f f_{t-1}^0 + u_t$, where $u_t \sim \text{iid}\mathcal{N}(0, (1 - \rho_f^2)\sigma_f^2)$, and σ_f is the standard deviation of f_t^0 . For all simulations we generate 1000 initial time periods for f_t^0 and Y_{it} that are not used for estimation. This guarantees that the simulated data used for estimation is distributed according to the stationary distribution of the model.

In this setup there is no correlation and heteroscedasticity in e_{it} , i.e. only the bias term B_1 of the LS estimator is non-zero, but we ignore this information in the estimation, i.e. we correct for all three bias terms (B_1 , B_2 , and B_3 , as introduced in Assumption 6) in the bias corrected LS estimator.

Table 1 shows the simulation results for the bias, standard error and root mean square error of the three different estimators for the case $N = 100$, $\rho_f = 0.5$, $\sigma_f = 0.5$, and different values of ρ^0 and T . As expected, the OLS estimator is biased due to the factor structure and its bias does not vanish (it actually increases) as T increases. The FLS estimator is also biased, but as predicted by the theory its bias vanishes as T increases. The bias corrected FLS estimator performs better than the non-corrected FLS estimator, in particular its bias vanishes faster. Since we only correct for the first order bias of the FLS estimator, we could not expect the bias corrected FLS estimator to be unbiased. However, as T gets larger more and more of the LS estimator bias is corrected for, e.g. for $\rho^0 = 0.3$ we find that at $T = 5$ the bias correction only corrects for about half of the bias, while at $T = 80$ it already corrects for about 90% of it.

Table 2 is very similar to Table 1, with the only difference that we allow for misspecification in the number of factors R , namely the true number of factors is assumed to be $R = 1$ (i.e. same DGP as for Table 1), but we incorrectly use $R = 2$ factors when calculating the FLS and

BC-FLS estimator. By comparing Table 2 with Table 1 we find that this type of misspecification of the number of factors increases the bias and the standard deviation of both the FLS and the BC-FLS estimator at finite sample. That increase, however, is comparatively small once both N and T are large. According to the results in Moon and Weidner (2013) we expect the limiting distribution of the correctly specified ($R = 1$) and incorrectly specified ($R = 2$) FLS estimator to be identical when N and T grow at the same rate. Our simulations suggest that the same is true for the BC-FLS estimator. The remaining simulation all assume correctly specified $R = 1$.

An import issue is the choice of bandwidth M for the bias correction. Table 3 gives the fraction of the FLS estimator bias that is captured by the estimator for the bias in a model with $N = 100$, $T = 20$, $\rho_f = 0.5$, $\sigma_f = 0.5$ and different values for ρ and M . The table shows that the optimal bandwidth (in the sense that most of the bias is corrected for) depends on ρ^0 : it is $M = 1$ for $\rho = 0$, $M = 2$ for $\rho = 0.3$, $M = 3$ and $\rho = 0.6$, and $M = 5$ for $\rho = 0.9$. Choosing the bandwidth too large or too small results in a smaller fraction of the bias to be corrected. Table 4 also reports the properties of the BC-FLS estimator for different values of ρ^0 , T and M . It shows that the effect of the bandwidth choice on the standard deviation of the BC-FLS estimator is relatively small at $T = 40$, but is more pronounced at $T = 20$. The issue of optimal bandwidth choice is therefore an important topic for future research. In the simulation results presented here we tried to choose reasonable values for M , but made no attempt of optimizing the bandwidth.

In our setup we have $\|\lambda^0 f^{0'}\| \approx \sqrt{2NT}\sigma_f$ and $\|e\| \approx \sqrt{N} + \sqrt{T}$.¹⁸ Assumption 1 and 3 imply that asymptotically $\|\lambda^0 f^{0'}\| \gg \|e\|$. We can therefore only be sure that our asymptotic results for the FLS estimator distribution are a good approximation of the finite sample properties if $\|\lambda^0 f^{0'}\| \gtrsim \|e\|$, i.e. if $\sqrt{2NT}\sigma_f \gtrsim \sqrt{N} + \sqrt{T}$. To explore this we present in Table 5 simulation results for $N = 100$, $T = 20$, $\rho^0 = 0.6$, and different values of ρ_f and σ_f . For $\sigma_f = 0$ we have $0 = \|\lambda^0 f^{0'}\| \ll \|e\|$, and this case is equivalent to $R = 0$ (no factor at all). In this case the OLS estimator estimates the true model and is almost unbiased, and correspondingly the FLS estimator and the bias corrected FLS estimator perform worse than OLS at finite sample (though we expect that all three estimators are asymptotically equivalent), but the bias corrected FLS estimator has a lower bias and a lower variance than the non-corrected FLS estimator. The case $\sigma_f = 0.2$ corresponds to $\|\lambda^0 f^{0'}\| \approx \|e\|$, and one finds that the bias and the variance of the OLS estimator and of the LS estimator are of comparable size. However, the bias corrected FLS estimator already has much smaller bias and a bit smaller variance in this case. Finally, in the case $\sigma_f = 0.5$ we have $\|\lambda^0 f^{0'}\| > \|e\|$, and we expect our asymptotic results to be a good approximation of this situation. Indeed, one finds that for $\sigma_f = 0.5$ the OLS estimator

is heavily biased and very inefficient compared to the FLS estimator, while the bias corrected FLS estimator performs even better in terms of bias and variance.

In Table 6 we present simulation results for the size of the various tests discussed in the last section when testing the Null hypothesis $H_0 : \rho = \rho^0$. We choose a nominal size of 5%, $\rho_f = 0.5$, $\sigma_f = 0.5$, and different values for ρ^0 , N and T . In all cases, the size distortions of the uncorrected Wald, LR and LM test are rather large, and the size distortions of these test do not vanish as N and T increase: the size for $N = 100$ and $T = 20$ is about the same as for $N = 400$ and $T = 80$, and the size for $N = 400$ and $T = 20$ is about the same as for $N = 1600$ and $T = 80$. In contrast, the size distortions for the bias corrected Wald, LR, and LM test are much smaller, and tend to zero (i.e. the size becomes closer to 5%) as N, T increase, holding the ratio N/T constant. For fixed T an increase in N results in a larger size distortion, while for fixed N an increase in T results in a smaller size distortion (both for the non-corrected and for the bias corrected tests).

In Table 7 and 8 we present the power and the size corrected power when testing the left sided alternative $H_a^{\text{left}} : \rho = \rho^0 - (NT)^{-1/2}$ and the right-sided alternative $H_a^{\text{right}} : \rho = \rho^0 + (NT)^{-1/2}$. The model specifications are the same as for the size results in table 4. Since both the FLS estimator and the bias corrected FLS estimator for ρ have a negative bias one finds the power for the left-sided alternative to be much smaller than the power for the right-sided alternative. For the uncorrected tests this effect can be extreme and the size-corrected power of these tests for the left sided alternative is below 2% in all cases, and does not improve as N and T become large, holding N/T fixed. In contrast, the power for the bias corrected tests becomes more symmetric as N and T become large, and the size-corrected power for the left sided alternative is much larger than for the uncorrected tests, while the size corrected power for the right sided alternative is about the same.

8 Conclusions

This paper studies the least squares estimator for dynamic linear panel regression models with interactive fixed effects. We provide conditions under which the estimator is consistent, allowing for predetermined regressors, and for a general combination of “low-rank” and “high-rank” regressors. We then show how a quadratic approximation of the profile objective function $L_{NT}(\beta)$ can be used to derive the first order asymptotic theory of the LS estimator of β under the alternative asymptotic $N, T \rightarrow \infty$. We find that the asymptotic distribution of the LS estimator can be asymptotically biased (i) due to weak exogeneity of the regressors and (ii) due and

heteroscedasticity (and correlation) of the idiosyncratic errors e_{it} . Consistent estimators for the asymptotic covariance matrix and for the asymptotic bias of the LS estimator are provided, and thus a bias corrected LS estimator is given. We furthermore study the asymptotic distributions of the Wald, LR and LM test statistics for testing a general linear hypothesis on β . The uncorrected test statistics are not asymptotically chi-square due to the asymptotic bias of the score and of the LS estimator, but bias corrected test statistics that are asymptotically chi-square distributed can be constructed. A possible extensions of the estimation procedure to the case of endogeneous regressors is also discussed. The findings of our Monte Carlo simulations show that our asymptotic results on the distribution of the (bias corrected) LS estimator and of the (bias corrected) test statistics provide a good approximation of their finite sample properties. Although the bias corrected LS estimator has a non-zero bias at finite sample, this bias is much smaller than the one of the LS estimator. Analogously, the size distortions and power asymmetries of the bias corrected Wald, LR and LM test are much smaller than for the non-bias corrected versions.

Appendix

A Proof of Consistency (Theorem 3.1)

The following theorem is useful for the consistency proof and beyond.

Lemma A.1. *Let N , T , R , R_1 and R_2 be positive integers such that $R \leq N$, $R \leq T$, and $R = R_1 + R_2$. Let Z be an $N \times T$ matrix, λ be an $N \times R$, f be a $T \times R$ matrix, $\tilde{\lambda}$ be an $N \times R_1$ matrix, and \tilde{f} be a $T \times R_2$ matrix. Then the following six expressions (that are functions of Z only) are equivalent:*

$$\begin{aligned} \min_{f, \lambda} \text{Tr} [(Z - \lambda f') (Z' - f \lambda')] &= \min_f \text{Tr} (Z M_f Z') = \min_{\lambda} \text{Tr} (Z' M_{\lambda} Z) \\ &= \min_{\tilde{\lambda}, \tilde{f}} \text{Tr} (M_{\tilde{\lambda}} Z M_{\tilde{f}} Z') = \sum_{i=R+1}^T \mu_i (Z' Z) = \sum_{i=R+1}^N \mu_i (Z Z') \end{aligned}$$

In the above minimization problems we do not have to restrict the matrices λ , f , $\tilde{\lambda}$ and \tilde{f} to be of full rank. If for example λ is not of full rank, then the generalized inverse $(\lambda' \lambda)^{\dagger}$ is still well defined, and the projector M_{λ} is still satisfied $M_{\lambda} \lambda = 0$ and $\text{rank}(M_{\lambda}) = N - \text{rank}(\lambda)$. If $\text{rank}(Z) \geq R$ then the optimal λ , f , $\tilde{\lambda}$ and \tilde{f} always have full rank.

Lemma A.1 shows the equivalence of the three different versions of the profile objective function in equation (4). It goes beyond this by also considering minimization of $\text{Tr}(M_{\tilde{\lambda}} Z M_{\tilde{f}} Z')$

over $\tilde{\lambda}$ and \tilde{f} , which will be used in the consistency proof below. The proof of the theorem is given in the supplementary material. The following lemma is due to Bai (2009).

Lemma A.2. *Under the assumptions of Theorem 3.1 we have*

$$\sup_f \left| \frac{\text{Tr}(X_k M_f e')}{NT} \right| = o_p(1), \quad \sup_f \left| \frac{\text{Tr}(\lambda^0 f^{0'} M_f e')}{NT} \right| = o_p(1), \quad \sup_f \left| \frac{\text{Tr}(e P_f e')}{NT} \right| = o_p(1),$$

where the parameters f are $T \times R$ matrices with $\text{rank}(f) = R$.

Proof. By Assumption 2 we know that the first equation in Lemma A.2 is satisfied when replacing M_f by the identity matrix. So we are left to show $\max_f \left| \frac{1}{NT} \text{Tr}(\Xi e') \right| = o_p(1)$, where Ξ is either $X_k P_f$, $\lambda^0 f^{0'} M_f$, or $e P_f$. In all three cases we have $\|\Xi\|/\sqrt{NT} = \mathcal{O}_p(1)$ by Assumption 1, 3, and 4, respectively, and we have $\text{rank}(\Xi) \leq R$. We therefore find¹⁹

$$\sup_f \left| \frac{1}{NT} \text{Tr}(\Xi P_f e') \right| \leq R \frac{\|e\|}{\sqrt{NT}} \frac{\|\Xi\|}{\sqrt{NT}} = o_p(1).$$

■

Proof of Theorem 3.1. For the second version of the profile objective function in equation (4) we write $L_{NT}(\beta) = \min_f S_{NT}(\beta, f)$, where

$$S_{NT}(\beta, f) = \frac{1}{NT} \text{Tr} \left[\left(\lambda^0 f^{0'} + \sum_{k=1}^K (\beta_k^0 - \beta_k) X_k + e \right) M_f \left(\lambda^0 f^{0'} + \sum_{k=1}^K (\beta_k^0 - \beta_k) X_k + e \right)' \right].$$

We have $S_{NT}(\beta^0, f^0) = \frac{1}{NT} \text{Tr}(e M_{f^0} e')$. Using Lemma (A.2) we find that

$$\begin{aligned} S_{NT}(\beta, f) &= S_{NT}(\beta^0, f^0) + \tilde{S}_{NT}(\beta, f) \\ &\quad + \frac{2}{NT} \text{Tr} \left[\left(\lambda^0 f^{0'} + \sum_{k=1}^K (\beta_k^0 - \beta_k) X_k \right) M_f e' \right] + \frac{1}{NT} \text{Tr}(e (P_{f^0} - P_f) e') \\ &= S_{NT}(\beta^0, f^0) + \tilde{S}_{NT}(\beta, f) + o_p(\|\beta - \beta^0\|) + o_p(1), \end{aligned} \tag{12}$$

where we defined

$$\tilde{S}_{NT}(\beta, f) = \frac{1}{NT} \text{Tr} \left[\left(\lambda^0 f^{0'} + \sum_{k=1}^K (\beta_k^0 - \beta_k) X_k \right) M_f \left(\lambda^0 f^{0'} + \sum_{k=1}^K (\beta_k^0 - \beta_k) X_k \right)' \right].$$

Up to this point the consistency proof is almost equivalent to the one given in Bai (2009), but the remainder of the proof differs from Bai, since we allow for more general low-rank

regressors, and since we allow for high-rank and low-rank regressors simultaneously. We split $\tilde{S}_{NT}(\beta, f) = \tilde{S}_{NT}^{(1)}(\beta, f) + \tilde{S}_{NT}^{(2)}(\beta, f)$, where

$$\begin{aligned}\tilde{S}_{NT}^{(1)}(\beta, f) &= \frac{1}{NT} \operatorname{Tr} \left[\left(\lambda^0 f^{0'} + \sum_{k=1}^K (\beta_k^0 - \beta_k) X_k \right) M_f \left(\lambda^0 f^{0'} + \sum_{k=1}^K (\beta_k^0 - \beta_k) X_k \right)' M_{(\lambda^0, w)} \right] \\ &= \frac{1}{NT} \operatorname{Tr} \left[\left(\sum_{m=K_1+1}^K (\beta_m^0 - \beta_m) X_m \right) M_f \left(\sum_{m=K_1+1}^K (\beta_m^0 - \beta_m) X_m \right)' M_{(\lambda^0, w)} \right], \\ \tilde{S}_{NT}^{(2)}(\beta, f) &= \frac{1}{NT} \operatorname{Tr} \left[\left(\lambda^0 f^{0'} + \sum_{k=1}^K (\beta_k^0 - \beta_k) X_k \right) M_f \left(\lambda^0 f^{0'} + \sum_{k=1}^K (\beta_k^0 - \beta_k) X_k \right)' P_{(\lambda^0, w)} \right],\end{aligned}$$

and (λ^0, w) is the $N \times (R + K_1)$ matrix that is composed out of λ^0 and the $N \times K_1$ matrix w defined in Assumption 4. For $\tilde{S}_{NT}^{(1)}(\beta, f)$ we can apply Lemma A.1 with $\tilde{f} = f$ and $\tilde{\lambda} = (\lambda^0, w)$ (the R in the theorem is now $2R + K_1$) to find

$$\begin{aligned}\tilde{S}_{NT}^{(1)}(\beta, f) &\geq \frac{1}{NT} \sum_{i=2R+K_1+1}^N \mu_i \left[\left(\sum_{m=K_1+1}^K (\beta_m^0 - \beta_m) X_m \right) \left(\sum_{m=K_1+1}^K (\beta_m^0 - \beta_m) X_m \right)' \right] \\ &\geq b \|\beta^{\text{high}} - \beta^{0, \text{high}}\|^2, \quad \text{wpa1},\end{aligned}\tag{13}$$

where in the last step we used the existence of a constant $b > 0$ guaranteed by Assumption 4(ii)(a), and we introduced $\beta^{\text{high}} = (\beta_{K_1+1}, \dots, \beta_K)'$, which refers to the $K_2 \times 1$ parameter vector corresponding to the high-rank regressors. Similarly we define $\beta^{\text{low}} = (\beta_1, \dots, \beta_{K_1})'$ for the $K_1 \times 1$ parameter vector of low-rank regressors.

Using $P_{(\lambda^0, w)} = P_{(\lambda^0, w)} P_{(\lambda^0, w)}$ and the cyclicity of the trace we see that $\tilde{S}_{NT}^{(2)}(\beta, f)$ can be written as the trace of a positive definite matrix, and therefore $\tilde{S}_{NT}^{(2)}(\beta, f) \geq 0$. Note also that we can choose $\beta = \beta^0$ and $f = f^0$ in the minimization problem over $S_{NT}(\beta, f)$, i.e. the optimal $\beta = \hat{\beta}$ and $f = \hat{f}$ must satisfy $S_{NT}(\hat{\beta}, \hat{f}) \leq S_{NT}(\beta^0, f^0)$. Using this, equation (12), $\tilde{S}_{NT}^{(2)}(\beta, f) \geq 0$, and the bound in (13) we find

$$0 \geq b \|\hat{\beta}^{\text{high}} - \beta^{0, \text{high}}\|^2 + o_p \left(\|\hat{\beta}^{\text{high}} - \beta^{0, \text{high}}\| \right) + o_p \left(\|\hat{\beta}^{\text{low}} - \beta^{0, \text{low}}\| \right) + o_p(1).$$

Since we assume that $\hat{\beta}^{\text{low}}$ is bounded, the last equation implies that $\|\hat{\beta}^{\text{high}} - \beta^{0, \text{high}}\| = o_p(1)$, i.e. $\hat{\beta}^{\text{high}}$ is consistent. What is left to show is that $\hat{\beta}^{\text{low}}$ is consistent, too. In the supplementary material we show that Assumption 4(ii)(b) guarantees that there exist finite positive constants a_0, a_1, a_2, a_3 and a_4 such that

$$\begin{aligned}\tilde{S}_{NT}^{(2)}(\beta, f) &\geq \frac{a_0 \|\beta^{\text{low}} - \beta^{0, \text{low}}\|^2}{\|\beta^{\text{low}} - \beta^{0, \text{low}}\|^2 + a_1 \|\beta^{\text{low}} - \beta^{0, \text{low}}\| + a_2} \\ &\quad - a_3 \|\beta^{\text{high}} - \beta^{0, \text{high}}\| - a_4 \|\beta^{\text{high}} - \beta^{0, \text{high}}\| \|\beta^{\text{low}} - \beta^{0, \text{low}}\|, \quad \text{wpa1}.\end{aligned}$$

Using consistency of $\widehat{\beta}^{\text{high}}$ and again boundedness of β^{low} this implies that there exists $a > 0$ such that $\widetilde{S}_{NT}^{(2)}(\widehat{\beta}, f) \geq a \left\| \widehat{\beta}^{\text{low}} - \beta^{0,\text{low}} \right\|^2 + o_p(1)$. With the same argument as for $\widehat{\beta}^{\text{high}}$ we therefore find $\left\| \widehat{\beta}^{\text{low}} - \beta^{0,\text{low}} \right\| = o_p(1)$, i.e. $\widehat{\beta}^{\text{low}}$ is consistent. ■

B Proof of Limiting Distribution (Theorem 4.3)

Theorem 4.1 is from Moon and Weidner (2013), and the proof can be found there. Note that Assumption 4(i) implies $\|X_k\| = \mathcal{O}_p(\sqrt{NT})$, which is assumed in Moon and Weidner (2013). There, it is also assumed that $\|e\| = \mathcal{O}_p(\sqrt{\max(N, T)}) = \mathcal{O}_p(\sqrt{N})$, while we assume $\|e\| = o_p(\|N^{2/3}\|)$. It is, however, straightforward to verify that the proof of Theorem 4.1 is also valid under this weaker assumption.

The proof of Corollary 4.2 is also given in Moon and Weidner (2013). The proof requires consistency of $\widehat{\beta}$, which in the current paper is derived under weaker assumptions than in Moon and Weidner (2013), where no low-rank regressors are considered. Corollary 4.2 is therefore stated under weaker assumptions here, but the proof is unchanged. In the supplementary material we show that the assumptions of Corollary 4.2 already guarantee that W_{NT} does not become singular as $N, T \rightarrow \infty$.

For each $k = 1, \dots, K$ we define the $N \times T$ matrices \overline{X}_k , \widetilde{X}_k and \mathfrak{X}_k as follows

$$\overline{X}_k = \mathbb{E}(X_k | \mathcal{C}), \quad \widetilde{X}_k = X_k - \mathbb{E}(X_k | \mathcal{C}), \quad \mathfrak{X}_k = M_{\lambda^0} \overline{X}_k M_{f^0} + \widetilde{X}_k.$$

Note the difference between \mathfrak{X}_k and $\mathcal{X}_k = M_{\lambda^0} X_k M_{f^0}$, which was defined in Assumption 6. In particular, conditional on \mathcal{C} , the elements $\mathfrak{X}_{k,it}$ of \mathfrak{X}_k are contemporaneously uncorrelated with the error term e_{it} , while the same is not true for \mathcal{X}_k .

To present the proof of Theorem 4.3 it is convenient to first state two technical lemmas.

Lemma B.1. *Under the assumptions of Theorem 4.3 we have*

$$\begin{aligned}
 (a) \quad & \frac{1}{\sqrt{NT}} \text{Tr} \left(P_{f^0} e' P_{\lambda^0} \tilde{X}_k \right) = o_p(1), \\
 (b) \quad & \frac{1}{\sqrt{NT}} \text{Tr} \left(P_{\lambda^0} e \tilde{X}'_k \right) = o_p(1), \\
 (c) \quad & \frac{1}{\sqrt{NT}} \text{Tr} \left\{ P_{f^0} \left[e' \tilde{X}_k - \mathbb{E} \left(e' \tilde{X}_k \mid \mathcal{C} \right) \right] \right\} = o_p(1), \\
 (d) \quad & \frac{1}{\sqrt{NT}} \text{Tr} \left(e P_{f^0} e' M_{\lambda^0} X_k f^0 (f^{0'} f^0)^{-1} (\lambda^{0'} \lambda^0)^{-1} \lambda^{0'} \right) = o_p(1), \\
 (e) \quad & \frac{1}{\sqrt{NT}} \text{Tr} \left(e' P_{\lambda^0} e M_{f^0} X'_k \lambda^0 (\lambda^{0'} \lambda^0)^{-1} (f^{0'} f^0)^{-1} f^{0'} \right) = o_p(1), \\
 (f) \quad & \frac{1}{\sqrt{NT}} \text{Tr} \left(e' M_{\lambda^0} X_k M_{f^0} e' \lambda^0 (\lambda^{0'} \lambda^0)^{-1} (f^{0'} f^0)^{-1} f^{0'} \right) = o_p(1), \\
 (g) \quad & \frac{1}{\sqrt{NT}} \text{Tr} \left\{ [e e' - \mathbb{E}(e e' \mid \mathcal{C})] M_{\lambda^0} X_k f^0 (f^{0'} f^0)^{-1} (\lambda^{0'} \lambda^0)^{-1} \lambda^{0'} \right\} = o_p(1), \\
 (h) \quad & \frac{1}{\sqrt{NT}} \text{Tr} \left\{ [e' e - \mathbb{E}(e' e \mid \mathcal{C})] M_{f^0} X'_k \lambda^0 (\lambda^{0'} \lambda^0)^{-1} (f^{0'} f^0)^{-1} f^{0'} \right\} = o_p(1), \\
 (i) \quad & \frac{1}{NT} \sum_{i=1}^N \sum_{t=1}^T [e_{it}^2 \mathfrak{x}_{it} \mathfrak{x}'_{it} - \mathbb{E}(e_{it}^2 \mathfrak{x}_{it} \mathfrak{x}'_{it} \mid \mathcal{C})] = o_p(1), \\
 (j) \quad & \frac{1}{NT} \sum_{i=1}^N \sum_{t=1}^T e_{it}^2 (\mathfrak{x}_{it} \mathfrak{x}'_{it} - \mathcal{X}_{it} \mathcal{X}'_{it}) = o_p(1).
 \end{aligned}$$

Lemma B.2. *Under the assumptions of Theorem 4.3 we have*

$$\frac{1}{\sqrt{NT}} \sum_{i=1}^N \sum_{t=1}^T e_{it} \mathfrak{x}_{it} \xrightarrow{d} \mathcal{N}(0, \Omega).$$

The proofs of Lemma B.1 and Lemma B.2 are provided in the supplementary material. We briefly want to discuss why the asymptotic variance-covariance matrix in Lemma B.2 turns out to be Ω . Note that since $e_{it} \mathfrak{x}_{it}$ is mean zero and uncorrelated across both i and t , conditional on \mathcal{C} , we have

$$\begin{aligned}
 \text{Var} \left(\frac{1}{\sqrt{NT}} \sum_{i=1}^N \sum_{t=1}^T e_{it} \mathfrak{x}_{it} \mid \mathcal{C} \right) &= \frac{1}{NT} \sum_{i=1}^N \sum_{t=1}^T \mathbb{E}(e_{it}^2 \mathfrak{x}_{it} \mathfrak{x}'_{it} \mid \mathcal{C}) \\
 &= \frac{1}{NT} \sum_{i=1}^N \sum_{t=1}^T e_{it}^2 \mathfrak{x}_{it} \mathfrak{x}'_{it} + o_p(1) \\
 &= \frac{1}{NT} \sum_{i=1}^N \sum_{t=1}^T e_{it}^2 \mathcal{X}_{it} \mathcal{X}'_{it} + o_p(1) \\
 &= \Omega + o_p(1),
 \end{aligned} \tag{14}$$

where we also used part (i) of Lemma B.1 for the second equality and part (j) of Lemma B.1 for the third equality, and the definition of Ω in Assumptions 5 in the last step.

Using those lemmas we can now prove the theorem on the limiting distribution of $\widehat{\beta}$ in the main text.

Proof of Theorem 4.3. Assumption 5 implies that $\|e\| = \mathcal{O}_p(N^{1/2})$ as N and T grow at the same rate, as discussed in Section S.2 of the supplementary material, i.e. Assumption 3* is satisfied. We can therefore apply Corollary 4.2 to calculate the limiting distribution of $\widehat{\beta}$. Note that $M_{\lambda^0} X_k M_{f^0} = \mathfrak{X}_k - \widetilde{X}_k P_{f^0} - P_{\lambda^0} \widetilde{X}_k + P_{\lambda^0} \widetilde{X}_k P_{f^0}$. Using Lemmas B.1 and B.2 and Assumption 6 we find

$$\begin{aligned}
 \frac{1}{\sqrt{NT}} C^{(1)}(\lambda^0, f^0, X_k, e) &= \frac{1}{\sqrt{NT}} \text{Tr}(e' M_{\lambda^0} X_k M_{f^0}) \\
 &= \frac{1}{\sqrt{NT}} \text{Tr}(e' \mathfrak{X}_k) - \frac{1}{\sqrt{NT}} \text{Tr} \left[P_{f^0} \mathbb{E} \left(e' \widetilde{X}_k \mid \mathcal{C} \right) \right] \\
 &\quad - \frac{1}{\sqrt{NT}} \text{Tr} \left(e' P_{\lambda^0} \widetilde{X}_k \right) + \frac{1}{\sqrt{NT}} \text{Tr} \left(P_{f^0} e' P_{\lambda^0} \widetilde{X}_k \right) \\
 &\quad - \frac{1}{\sqrt{NT}} \text{Tr} \left\{ P_{f^0} \left[e' \widetilde{X}_k - \mathbb{E} \left(e' \widetilde{X}_k \mid \mathcal{C} \right) \right] \right\} \\
 &= \frac{1}{\sqrt{NT}} \text{Tr}(e' \mathfrak{X}_k) - \frac{1}{\sqrt{NT}} \text{Tr} \left[P_{f^0} \mathbb{E} \left(e' X_k \mid \mathcal{C} \right) \right] + o_p(1) . \\
 &\xrightarrow{d} \mathcal{N}(-\kappa B_1, \Omega) ,
 \end{aligned}$$

where we also used that $\mathbb{E}(e' \tilde{X}_k | \mathcal{C}) = \mathbb{E}(e' X_k | \mathcal{C})$. Using Lemma B.1 we also find

$$\begin{aligned}
 \frac{1}{\sqrt{NT}} C^{(2)}(\lambda^0, f^0, X_k, e) &= - \frac{1}{\sqrt{NT}} \left[\text{Tr}(e M_{f^0} e' M_{\lambda^0} X_k f^0 (f^{0'} f^0)^{-1} (\lambda^{0'} \lambda^0)^{-1} \lambda^{0'}) \right. \\
 &\quad + \text{Tr}(e' M_{\lambda^0} e M_{f^0} X_k' \lambda^0 (\lambda^{0'} \lambda^0)^{-1} (f^{0'} f^0)^{-1} f^{0'}) \\
 &\quad \left. + \text{Tr}(e' M_{\lambda^0} X_k M_{f^0} e' \lambda^0 (\lambda^{0'} \lambda^0)^{-1} (f^{0'} f^0)^{-1} f^{0'}) \right] \\
 &= \frac{1}{\sqrt{NT}} \text{Tr}(e P_{f^0} e' M_{\lambda^0} X_k f^0 (f^{0'} f^0)^{-1} (\lambda^{0'} \lambda^0)^{-1} \lambda^{0'}) \\
 &\quad - \frac{1}{\sqrt{NT}} \text{Tr}\{[ee' - \mathbb{E}(ee' | \mathcal{C})] M_{\lambda^0} X_k f^0 (f^{0'} f^0)^{-1} (\lambda^{0'} \lambda^0)^{-1} \lambda^{0'}\} \\
 &\quad - \frac{1}{\sqrt{NT}} \text{Tr}[\mathbb{E}(ee' | \mathcal{C}) M_{\lambda^0} X_k f^0 (f^{0'} f^0)^{-1} (\lambda^{0'} \lambda^0)^{-1} \lambda^{0'}] \\
 &\quad + \frac{1}{\sqrt{NT}} \text{Tr}(e' P_{\lambda^0} e M_{f^0} X_k' \lambda^0 (\lambda^{0'} \lambda^0)^{-1} (f^{0'} f^0)^{-1} f^{0'}) \\
 &\quad - \frac{1}{\sqrt{NT}} \text{Tr}\{[e'e - \mathbb{E}(e'e | \mathcal{C})] M_{f^0} X_k' \lambda^0 (\lambda^{0'} \lambda^0)^{-1} (f^{0'} f^0)^{-1} f^{0'}\} \\
 &\quad - \frac{1}{\sqrt{NT}} \text{Tr}[\mathbb{E}(e'e | \mathcal{C}) M_{f^0} X_k' \lambda^0 (\lambda^{0'} \lambda^0)^{-1} (f^{0'} f^0)^{-1} f^{0'}] \\
 &\quad + \frac{1}{\sqrt{NT}} \text{Tr}(e' M_{\lambda^0} X_k M_{f^0} e' \lambda^0 (\lambda^{0'} \lambda^0)^{-1} (f^{0'} f^0)^{-1} f^{0'}) \\
 &= - \frac{1}{\sqrt{NT}} \text{Tr}[\mathbb{E}(ee' | \mathcal{C}) M_{\lambda^0} X_k f^0 (f^{0'} f^0)^{-1} (\lambda^{0'} \lambda^0)^{-1} \lambda^{0'}] \\
 &\quad - \frac{1}{\sqrt{NT}} \text{Tr}[\mathbb{E}(e'e | \mathcal{C}) M_{f^0} X_k' \lambda^0 (\lambda^{0'} \lambda^0)^{-1} (f^{0'} f^0)^{-1} f^{0'}] + o_p(1), \\
 &= - \kappa^{-1} B_2 - \kappa B_3 + o_p(1).
 \end{aligned}$$

Combining these results we obtain

$$\begin{aligned}
 \sqrt{NT} (\hat{\beta} - \beta^0) &= W_{NT}^{-1} \frac{1}{\sqrt{NT}} C_{NT} \\
 &\xrightarrow{d} \mathcal{N}(-W^{-1} (\kappa B_1 + \kappa^{-1} B_2 + \kappa B_3), W^{-1} \Omega W^{-1}),
 \end{aligned}$$

which is what we wanted to show. ■

Notes

¹See, e.g., Chamberlain and Rothschild (1983), Ross (1976), and Fama and French (1993) for asset pricing; Stock and Watson (2002) and Bai and Ng (2006) for forecasting; Bernanke, Boivin and Elias (2005) for empirical macro; and Holtz-Eakin, Newey, and Rosen (1988) for empirical labor economics.

²The theory of the CCE estimator was further developed in e.g. Harding and Lamarche (2009; 2011), Kapetanios, Pesaran and Yamagata (2011), Pesaran and Tosetti (2011), Chudik, Pesaran and Tosetti (2011), and Chudik and Pesaran (2013).

³The LS estimator is sometimes called “concentrated” least squares estimator in the literature, and in an earlier version of the paper we referred to it as the “Gaussian Quasi Maximum Likelihood Estimator”, since LS estimation is equivalent to maximizing a conditional Gaussian likelihood function.

⁴This alternative asymptotic is known to be a convenient tool in the fixed effect panel literature to characterize the asymptotic bias due to incidental parameter problems. See Arellano and Hahn (2007) and Moon, Perron and Phillips (2014) and references therein.

⁵The “likelihood ratio” and the score used in the tests are based on the LS objective function, which can be interpreted as the (misspecified) conditional Gaussian likelihood function.

⁶Another type of widely studied tests in the interactive fixed effect panel literature are panel unit root test, e.g., Bai and Ng (2004), Moon and Perron (2004), and Phillips and Sul (2003).

⁷Lee, Moon, and Weidner (2012) also apply the MSW estimation method to estimate a simple dynamic panel regression with interactive fixed effect and classical measurement errors.

⁸To remove this restriction, one could estimate R consistently in the presence of the regressors. In the literature so far, however, consistent estimation procedures for R are established mostly in pure factor models (e.g., Bai and Ng (2002), Onatski (2005) and Harding (2007)). Alternatively, one could rely on Moon and Weidner (2013) who consider a regression model with interactive fixed effects when only an upper bound on the number of factors is known — but it is mathematically very challenging to extend those results to the more general setup considered here.

⁹If we have low-rank regressors with rank larger than one, then we write $X_l = w_l v_l'$, where w_l is an $N \times \text{rank}(X_l)$ matrix and v_l is a $T \times \text{rank}(X_l)$ matrix, and we define $w = (w_1, \dots, w_{K_1})$ as a $N \times \sum_{l=1}^L \text{rank}(X_l)$ matrix, and $v = (v_1, \dots, v_{K_1})$ as a $T \times \sum_{l=1}^L \text{rank}(X_l)$ matrix. All our results would then be unchanged, as long as $\text{rank}(X_l)$ is a finite constant for all $l = 1, \dots, K_1$, and we replace $2R + K_1$ by $2R + \text{rank}(w)$ in Assumption ID(v) and Assumption 4(ii)(a).

¹⁰Note that $\text{rank}(\lambda^0) = R$ if R factors are present. Our identification results are consistent with the possibility that $\text{rank}(\lambda^0) < R$, i.e. that R only represents an upper bound on the number of factors, but later we assume $\text{rank}(\lambda^0) = R$ to show consistency.

¹¹We could write $X_k^{(N,T)}$, $e^{(N,T)}$, $\lambda^{(N,T)}$ and $f^{(N,T)}$, because all these matrices, and even their dimensions, are functions on N and T , but we suppress this dependence throughout the paper.

¹²Here and in the following we write $\sigma(A)$ for the sigma algebra generated by the (collection of) random variable(s) A , and we write $\mathcal{A} \vee \mathcal{B}$ for the sigma algebra generated by the unions of all elements in the sigma algebra \mathcal{A} and \mathcal{B} , so that in the conditional expectation in Assumption 5(ii) we condition jointly on \mathcal{C} and $\{(X_{is}, e_{i,s-1}), s \leq t\}$.

¹³Assumption 2 and 3* are implied by Assumption 5 and therefore need not be explicitly assumed here.

¹⁴Alternatively, one could use $\widehat{B}(\widetilde{\beta})$ and $\widehat{W}(\widetilde{\beta})$ as estimates for B and W , and would obtain the same limiting distribution of LR_{NT}^* under the null hypothesis H_0 . These alternative estimators are not consistent if H_0 is false, i.e. the power-properties of the test would be different. The question which specification should be preferred is left for future research.

¹⁵The proof of the statement is given in the supplementary material as part of the proof of Theorem 5.2.

¹⁶Chernozhukov and Hansen (2005) also used a similar method for estimating endogenous quantile regression models.

¹⁷Here we can either use $\mathbb{B} = (-1, 1)$, or $\mathbb{B} = \mathbb{R}$. In the present model we only have high-rank regressors, i.e. the parameter space need not be bounded to show consistency.

¹⁸To be precise, we have $\|\lambda^0 f^{0'}\|/(\sqrt{2NT}\sigma_f) \rightarrow_p 1$, and $\|e\|/(\sqrt{N} + \sqrt{T}) \rightarrow_p 1$.

¹⁹Here we use $|\text{Tr}(C)| \leq \|C\| \text{rank}(C)$, which holds for all square matrices C , see the supplementary material.

Table 1: Simulation results for the AR(1) model described in the main text with $N = 100$, $\rho_f = 0.5$, $\sigma_f = 0.5$, and different values of T (with corresponding bandwidth M) and true AR(1) coefficient ρ^0 . The OLS estimator, the LS estimator with factors (FLS, computed with correct $R = 1$), and corresponding bias corrected LS estimator with factors (BC-FLS) were computed for 10,000 simulation runs. The table lists the mean bias, the standard deviation (std), and the square root of the mean square error (rmse) for the three estimators.

Table 3: Simulation results for the AR(1) model with $N = 100$, $T = 20$, $\rho_f = 0.5$, and $\sigma_f = 0.5$. For different values of the AR(1) coefficient ρ^0 and of the bandwidth M , we give the fraction of the LS estimator bias that is accounted for by the bias correction, i.e. the fraction $\sqrt{NT} \mathbb{E}(\widehat{\beta} - \beta) / \mathbb{E}(\widehat{W}^{-1} \widehat{B})$, computed over 10,000 simulation runs. Here and in all following tables it is assumed that $R = 1$ is correctly specified.
