FOREWORD

Other financial intermediaries except insurance corporations and pension funds (OFIs) have gained considerable importance over the last few years. However, in spite of this, the literature shows that there is still little understanding of the business undertaken by OFIs and its implications for money demand. Consequently, the impact of OFIs on monetary and credit developments is increasingly attracting the attention of central banks. Against this background, on 23 March 2006, the Monetary Policy Stance Division of the ECB’s Directorate Monetary Policy held an expert meeting with national central banks (NCBs) of the European System of Central Banks on the role of OFIs in euro area monetary and credit developments. The meeting discussed a number of key issues that were seen as being of particular relevance. This study presents the results of the analytical work carried out in preparation for the aforementioned NCB expert meeting. It therefore presents a unique compilation of material based on aggregate euro area data and cross-country evidence for the assessment of sectoral monetary developments.
Monetary growth has increased significantly in the euro area in recent years, raising concerns about the risks to price stability. Viewed from a sectoral perspective, this increase reflects to a large extent the deposit holdings of other financial intermediaries (OFIs).

This paper presents analytical work on the role of OFIs in monetary and credit developments in the euro area.

Although, at the moment, some shortcomings in the data available – such as the lack of long time series data – seriously limit the analysis of the role of OFIs in monetary and credit aggregates, it seems clear that OFIs have gained considerable importance in recent years, not only as a factor affecting monetary developments, but also for the functioning of the financial system. This gain in importance may be due to financial deregulation and liberalisation, as well as financial innovation. These developments are reflected in the integration and deepening of euro area financial markets, as well as in investors’ attitude to risk.

A more detailed analysis that builds on descriptive statistical techniques reveals that OFIs constitute a very heterogeneous group of institutions, with investment funds (other than money market funds) being the main money holders among the OFI sub-sectors.

At the euro area level, reflecting the nature of their business, OFIs seem to favour instruments within M3 with a stronger financial market orientation, while also exhibiting a significant share of cross-border deposit holdings. In practice, they follow quite different investment practices, a fact which needs to be taken into account when analysing the implications for the behaviour of monetary aggregates.

Finally, OFIs’ activities may have a relatively small direct impact on final demand for goods and services. It can therefore be questioned whether the inclusion of short-term deposits and repurchase agreements held by OFIs within M3 may affect the information content of the monetary aggregate for assessing inflationary pressures in the economy. But, in order to come to a final assessment, not only these direct but also the indirect linkages with other sectors and other key economic variables, such as asset prices, need to be investigated.

Against this background, gaining a deeper understanding of the reasons why OFIs hold liquid deposits and the implications of this behaviour will remain an important aspect of monetary analysis.
I  INTRODUCTION

Money held by financial intermediaries other than monetary financial institutions (MFIs) has become much more important in the analysis of monetary developments over the past decade. This is particularly true for the OFI sector, i.e. non-MFI financial intermediaries other than insurance corporations and pension funds. OFIs typically provide financial services to households and non-financial corporations and/or trade in financial markets on their own behalf. The sector also includes institutions created by MFIs to facilitate the securitisation of loans that would otherwise be held on the MFI balance sheet.

The key difference between OFIs and MFIs is that the latter can take deposits from the public, while the OFIs are financed by other means, e.g. by issuing securities. OFIs are subject to less stringent regulatory requirements; in particular they often need to set aside less capital than MFIs for prudential supervisory purposes. Additionally, in some countries, OFIs may also benefit from special tax treatment, which may render the conduct of certain financial operations in a separate entity outside the MFI sector attractive.

Since OFIs are often subject to a lighter regulatory burden, they may adopt financial innovations faster than MFIs. MFIs may establish non-deposit taking financial subsidiaries precisely for the purpose of implementing financial innovation, for instance, special purpose vehicles created to securitise MFI loans. OFIs may also represent an efficient solution for specialised financial activities, e.g. credit card issuance. Therefore, at least in part, the increased importance of this sector for monetary analysis reflects financial liberalisation and innovation, as well as the associated development of deeper and more liquid securities markets.

The remainder of this paper is organised as follows. Section 2 presents the statistical framework for the OFI sector. It provides institutional information on the sub-categories of the OFI sector, presents the relative importance of the main assets and liabilities in the balance sheet for the individual sub-categories and highlights the transactions that the different types of OFIs typically undertake with MFIs. Section 3 addresses the relevance of the OFI sector from a monetary analysis perspective, looking in particular at its money-holding behaviour at the euro area level and the impact of OFIs’ money holdings for the indicator properties of money. In order to show the full breadth of the heterogeneity of the OFI sector, Section 4 provides a detailed analysis of OFIs’ money holdings at the country level. Section 5 concludes.
2 OFIs AND THEIR RELATIONSHIPS WITH MFIs

by A. Matas Mir, J. Matilainen and P. Poloni (ECB staff)

In light of the recent growth in OFIs’ money holdings, this section defines the entities constituting the OFI sector, presents in a schematic manner the typical activities undertaken by the different OFI sub-sectors and flags the cases where financial liquid positions with MFIs may arise from their activity. Against this background, evidence is provided on the impact of the financial behaviour of various types of OFI on the MFI balance sheet. While these sub-categories are reflected in statistical definitions that are meant to clearly define their parameters, the sub-categories are described in a non-technical manner and practical examples provided.

2.1 ACTIVITIES OF THE VARIOUS OFI SUB-CATEGORIES

The OFI sector is heterogeneous in itself, basically consisting of a range of very different entities. The five most important categories are: 1) investment funds, 2) financial corporations engaged in lending (financial leasing, factoring, consumer credit, etc.), 3) financial vehicle corporations, 4) financial holding corporations and 5) securities and derivatives dealers.

In order to give an overview of the different business models, the five main different sub-categories are defined and institutional aspects are briefly presented below.

2.1.1 INVESTMENT FUNDS

An investment fund (IF) is a financial investment vehicle which is aimed at private investors – little or large – or institutional investors. Such investment funds use capital raised from the public to acquire financial and non-financial assets for their shareholders. Households and firms thus pool their savings. The benefit of investment funds is essentially that they offer everybody – whether professional or institutional investors, or people with limited time or modest means – access to investment returns that would otherwise only be available to more sophisticated investors able to buy their own professional portfolio management advice. Investment funds offer economies of scale, and generally entail less risk than direct holdings of securities.

At the same time, IFs are institutional investors that provide a source of funding (both credit and equity) to non-financial corporations and governments. The units/shares of these investment funds are, at the request of the holders, repurchased or redeemed directly or indirectly out of the investment fund’s assets, and, in the case of those investment funds that have a fixed number of shares, the holders entering or leaving the investment funds must buy or sell existing shares.

Investment funds can be further distinguished according to their main type of investment policy as equity funds, bond funds, mixed funds, real estate funds, hedge funds, and “other funds”. Among the group of “other funds”, in recent months, venture capital funds have attracted significant public attention. However, when analysing the behaviour of the overall category of euro area investment funds, hedge funds and venture capital funds play only a subordinate role.

2.1.2 FINANCIAL VEHICLE CORPORATIONS

A financial vehicle corporation (FVC) is an undertaking that predominantly carries out one or more securitisations. The term “securitisation”

1 Except insurance companies and pension funds (ICPFs).
2 There is also a sixth, residual sub-category which comprises any other financial intermediary other than MFIs, insurance corporations and pension funds (ICPF). Examples of OFIs in this sub-category are certain clearing houses, venture capital companies not structured as investment funds, financial holding companies whose participation interest are mainly in non-financial companies, and investment companies not open to the public.
3 This classification is made according to Guideline ECB/2007/9 for the reporting of assets and liabilities by the IF sector.
4 According to data from the European Fund and Asset Management Association (EFAMA) on the net asset value of investment funds in a number of Member States (namely Belgium, Germany, Greece, Spain, France, Italy, Luxembourg, the Netherlands, Austria, Portugal and Finland), a conservative estimate indicates that approximately 5% of the asset value placed in investment funds is held with hedge funds and venture capital entities.
denotes a process whereby assets such as mortgage loans and corporate loans (or the risks associated with them) are pooled and repackaged as marketable securities (asset-backed securities) that can be sold to investors. There are two main types of securitisation: true-sale securitisation and synthetic securitisation. A true-sale securitisation takes place, for instance, when a bank (the originator) sells illiquid assets (e.g. loans, secured or not by mortgages) to a third party, which is often an FVC. The FVC finances the purchase by issuing securities, which are collateralised by the assets purchased from the bank. These asset-backed securities may be open to the public or sold on the basis of a private placement. A synthetic securitisation transfers the credit risk, but not the underlying assets, to the FVC. This is achieved by stipulating, for instance, a credit default swap between the originator and the FVC.

FVCs are often used by MFIs (and other originators) to mobilise loans and other non-tradable assets in exchange for cash. In other words, securitisations represent an alternative form of funding for the MFIs. Moreover, securitisations allow the required minimum capital that banks must respect for prudential purposes to be decreased. Regulatory and tax changes in the euro area have had a significant impact on the extent of the different securitisation activities in recent years.

2.1.3 FINANCIAL CORPORATIONS ENGAGED IN LENDING

A financial corporation engaged in lending (FCL) is an entity that specialises in granting loans, often focusing on a specialised market segment, and is financed by instruments other than deposits. This specialised market segment may be financial leasing, factoring, mortgage lending, consumer lending, credit card issuance and other types of lending as defined by EU and/or national regulatory provisions. An appropriate organisational and technical structure facilitates the granting of loans in these specific forms. For instance, a financial leasing company must be able to assess the value of the physical assets being leased in order to sell on the secondary market, or lease again the assets that have not been eventually purchased by their customers.

Unlike credit institutions, FCLs do not collect deposits to finance their lending activity. The financing of FCLs is therefore normally provided by MFIs, although some funds are also obtained by issuing debt securities. Most FCLs are not subject to specific supervisory rules although various FCLs are subject to consumer protection provisions.

2.1.4 FINANCIAL HOLDING CORPORATIONS

Financial holding corporations (FHCs) are entities principally engaged in controlling financial corporations or groups of subsidiary financial corporations and do not conduct the business of such financial corporations themselves. FHCs control a corporation by owning more than half of its voting shares or by controlling more than half of the shareholders’ voting power, or by otherwise being able to determine the general corporate policy, or by controlling entities that control financial corporations or groups of subsidiary financial corporations. Normally, a FHC does not actively trade in participation interests and has no permanent staff. They are entities created to structure the control of financial subsidiaries and to minimise the fiscal implications of the income generated by the subsidiaries.

2.1.5 SECURITIES AND DERIVATIVES DEALERS

Securities and derivatives dealers (SDDs) are firms that provide investment services for clients through brokerage, investing or market-making in securities and derivatives as their main business. The investment services provided include asset management advice, clearing and custody services as well as buying and selling of financial instruments for the sole purpose of benefiting from the margin between the acquisition and selling price. Securities and

---

5 This definition excludes MFIs as defined in Annex I of Regulation (EC) No 2423/2001 of the European Central Bank of 22 November 2001 concerning the consolidated balance sheet of the monetary financial institutions sector (ECB/2001/13) hereinafter “Regulation ECB/2001/13”.

---

ECB
Occasional Paper No 75
October 2007
derivative dealers may be subjected to the same prudential regulation as credit institutions as far as their market activities are concerned, and they are often subsidiaries of credit institutions. At the same time, MFIs also often provide the same investment services and trading activities. As mentioned above, the main difference between an SDD and an MFI is that the latter can collect deposits from the public, while an SDD cannot.

2.2 THE AVAILABLE STATISTICAL INFORMATION ON OFIs

There are currently two main statistical sources available for the analysis of the role of OFIs in monetary and credit developments in the euro area: unharmonised balance sheet data collected from OFIs and harmonised balance sheet statistics provided by MFIs.

As regards the first data source, the ECB collects quarterly balance sheet statistics on most OFI sub-categories. The data are collected from the euro area NCBs on the basis of unharmonised information available at the national level. As a minimum common denominator to facilitate data aggregation at the euro area level, the ECB has set out a reporting scheme for national data compilers. At the moment, however, not all the Member States are able to compile all requested breakdowns of this reporting scheme. Moreover, the coverage of the reporting population is below 100% in several countries.

The available balance sheet statistics on OFIs are collected for four OFI sub-categories: IFs, FCLs, SDDs and a residual category of other OFIs for which balance sheet information is available at the national level. Balance sheet data refer to stocks only and are broken down by instrument. Maturity and (sector and residency) counterpart breakdowns are available for a limited subset of instruments (i.e. for investment funds, securities holdings data are broken down by maturity and counterpart). Furthermore, investment funds data are broken down by investment policy and by type of investor (general public, special investors). Owing to limited data availability and quality, euro area aggregates are currently compiled and published only for IFs.

At present, in line with the requirements of Regulation ECB/2001/13, MFIs report balance sheet positions with OFIs, including deposit liabilities to OFIs. This facilitates the monitoring of OFIs’ holdings of deposits included in M3 and, hence, provides valuable information for monetary analysis purposes. However, it is difficult to relate these data on deposit holdings to the broad portfolio decisions of OFIs and capital market developments more generally. Furthermore, the function of the OFI sector as a counterpart to the portfolio shifts undertaken by private households, and the possible substitution of MFI loans for loans granted by OFIs (including through securitisation transactions) cannot be properly traced. Therefore, it has to be admitted that the usefulness of the currently available data for OFIs is rather limited.

Against this background and in view of the current shortcomings of the available information on OFIs, the ESCB is working towards a major overhaul. In particular, in order to improve the coverage of the OFI sector, the two most important sub-categories – namely IFs and FVCs – have been identified as being of particular interest. To this regard in July 2007, the ECB has enacted a regulation (ECB/2007/8) directed at investment funds in order to obtain a comprehensive picture of the assets and liabilities of the IF sector in the participating Member States. It is worth mentioning that FVC balance sheet statistics will also prove particularly important for monetary analysis with regard to the analysis of the links between MFIs and OFIs that arise through (traditional and, partly, synthetic) loan securitisations and

---

6 The definitions of these sub-sectors are described in the Guideline of the European Central Bank of 15 February 2005 amending Guideline ECB/2003/2 concerning certain statistical reporting requirements of the European Central Bank and the procedures for reporting by the national central banks of statistical information in the field of money and banking statistics. However, NCB compilers might in practice deviate from these definitions depending on national circumstances.
other loans sales. In this respect, enhanced FVC statistical information could lead to a significant improvement in the analysis of monetary and credit developments. This information could in turn provide a fuller picture of (changes in) MFI lending activity with the euro area money-holding sector and of the accumulation of FVC deposits placed with MFIs. This would therefore make the analysis of M3 and its counterparts considerably more comprehensive.

2.3 IMPACT OF OFIs’ FINANCIAL BEHAVIOUR ON THE MFI BALANCE SHEET

This section aims to review the main financial relations with MFIs in each of the five OFI sub-sectors. The heterogeneity of the business models has implications for the financial relationship between OFIs and MFIs, and thus for the pattern of money holdings across OFIs. While leasing companies are more likely to be net borrowers from the MFI sector, IFs and factoring firms are typically net depositors. For other institutions in the OFI sector, such as FVCs, the net position with MFIs is less clear cut. Table 1 compares the size of the OFI sub-categories with that of the consolidated euro area MFI sector and that of the insurance corporations and pension funds (ICPF) sector in the euro area. While the total assets of IFs refer to consolidated holdings (i.e. when IFs’ holdings of shares/units issued by other euro area IFs have been excluded), the total assets of the other four OFI sub-categories are simply aggregated. However, this is not expected to make a significant difference due to the low amount of business between institutions within the four sub-sectors. At the same time, entities belonging to one OFI sub-sector may hold assets issued by another OFI sub-sector, something which may be particularly relevant for IFs’ holdings of debt securities issued by FVCs. However, no data about these positions are available to allow for consolidation.

The data show that the MFI sector is significantly larger than all the OFI sub-categories combined. The largest sub-category, IFs, amounts to 25% of the MFI sector, while the other three are much smaller, constituting between 2% and 4%. Moreover, the ICPF sector, which is not discussed in this paper, seems to be of a similar size to the IF sector, when comparing their total financial assets. In relation to the annual euro area GDP, the total assets of MFIs amounted to 225% of GDP, while the total assets of IFs amounted to 56% (calculated as at mid-2006). Since the institutional coverage of the available OFI statistics is not complete, the size of the OFI sub-sectors shown in Table 1 is underestimated.

Given the propensity of OFIs to implement financial innovation, monitoring the relative size of the OFI sector (and sub-sectors) compared to the MFI sector might hint at financial developments that may alter the transmission mechanism of monetary policy and/or the interpretation of traditional balance sheet data. The growing significance of the OFI sector has been particularly evident since mid-2004, as

Note: The total assets of the residual category of other OFIs cannot be estimated.

1) For insurance corporations and pension funds, only financial assets are included.
2) For FVCs, data estimated on the basis of Italian data as at end-2004 (source: Working Group on Money, Financial Institutions and Markets Statistics), Dutch data as at the third quarter of 2005 (source: De Nederlandsche Bank) and market shares as at the third quarter of 2005 (source: www.europeansecuritisation.com). The Italian and Dutch market shares jointly represent 45% of the euro area.
3) For FHCs, the reference date is end-2003.
reflected in its contribution to the annual growth rate of short-term deposits\(^9\) including repurchase agreements (referred to here as M3 deposits) – the broadest aggregation of M3 components for which a sectoral breakdown is available (see Chart 1). In 2006, the OFI sector’s contribution to the 8.1% average annual growth rate amounted to 1.8 percentage points. This impact on monetary dynamics is particularly noteworthy, as OFIs in mid-2006 accounted for only around 11% of the total holdings of short-term deposits including repurchase agreements.

Chart 2 presents the relative importance of the main assets and liabilities in the balance sheet of four OFI sub-sectors (IFs, FVCs, SDDs and FCLs) for which balance sheet information is available.\(^10\) The charts also indicate – for each item in the OFI sub-sectors’ balance sheets which would typically include liquid financial positions with MFIs – an estimation of the importance of such liquid positions from most important (indicated with three asterisks) to least important (indicated with one asterisk). Owing to the insufficient level of counterparty/maturity breakdowns available in the data collected by the ECB under the short-term approach, such estimations have been derived mostly by considering the typical activity of each OFI sub-sector.\(^11\)

The main financial relations with MFIs are described separately for the assets side and for the liabilities side of the OFIs’ balance sheet, in terms of instrument categories. It is important to note that if OFIs’ intermediation activity was undertaken within the MFI sector then it would be consolidated in the money and banking statistics. As regards the assets side, a key question relates to the extent to which a given OFI sub-sector places deposits with MFIs or invests in other liquid assets issued by MFIs (such as debt securities or derivatives). As for the liabilities side, an important question is whether MFIs are a source of funding for OFIs and/or whether derivatives positions between OFIs and MFIs are in place. Given the limited availability of data, these questions will be addressed mainly from a qualitative perspective.

As far as IFs are concerned, transactions with MFIs typically engage the assets side of the balance sheet. Investment funds place deposits (including repos) with MFIs as a liquidity buffer against possible calls for repayment of shares/units issued. Additionally, the funds may hold deposits with MFIs as an inevitable part of the turnover process of their investment positions. Transactions in derivatives

---

\(^9\) Short-term deposits include overnight deposits, deposits with agreed maturity of up to two years (short-term time deposits) and deposits redeemable at notice up to three months (short-term savings deposits).

\(^10\) Data gaps and the limited availability of breakdowns on loans and deposits (e.g. absence of maturity, geographical and institutional counterparty breakdowns) result in unharmonised OFI data collected by the ECB and therefore complicate an empirical analysis of their relevance in overall monetary and credit developments reflected by the MFI data. This is further aggravated by the fact that the MFI data on loans and deposits refer to the aggregate OFI sector plus financial auxiliaries, with no breakdowns by OFI sub-sector available. We endeavour to overcome these difficulties by restricting our quantitative analysis to the country level and by focusing on MFIs’ transactions with domestic OFIs. This allows us to exploit the different relative importance of the various OFI sub-sectors in different countries as a set of identification restrictions.

\(^11\) A tentative empirical analysis is presented in the Annex on the basis of preliminary data available from the OFI statistics, linking (at the individual country level) developments in OFIs’ deposits and loans with data reported by the MFI balance sheet statistics.
Chart 2 Schematic presentation of main OFIs' short-term financial positions with MFIs

Items estimated to include liquid financial positions with MFIs are indicated with asterisks in the legend, with the number of asterisks indicating the degree of importance of such liquid positions based on a qualitative assessment (see text).

OFIs AND THEIR RELATIONSHIPS WITH MFIs

Looking at OFIs’ holdings of marketable securities included in M3, Chart 3 shows the estimated share of euro area IFs’ holdings of MFI debt securities with a maturity of up to one year in the total amount outstanding of such securities held by euro area residents other than MFIs. According to these estimates, the share of euro area IFs as holders of such securities has steadily gained in importance, from a share of slightly less than 20% in the fourth quarter of 1998 to slightly over 60% in the second quarter of 2006. The extent to which the share of IFs’ holdings of MFI debt securities with a maturity of over one and up to two years has seen a similar increase over the period cannot be determined from the available OFI short-term data, although such securities play a smaller role in M3.12 As for

12 The average share (January 1999 to December 2005) of MFI debt securities with a maturity of up to one year over total M3 is 1.6%, compared with 0.7% for those with a maturity of over one and up to two years.
money market fund shares/units, the proportion of IFs’ holdings in the total amount outstanding held by non-MFI euro area residents is much lower than in the case of debt securities, which is estimated at around 5%.

Turning to the liabilities side of IFs’ balance sheet, evidence of quantitatively significant relationships between IFs and MFIs is more limited, as IFs normally promote the sale of their shares/units to the public while, in general, loans and deposits play only a subordinate role. It cannot be ruled out that MFIs purchase shares of IFs’, especially in the most innovative asset classes, e.g. shares/units issued by hedge funds. Moreover, this latter type of fund may seek leverage by borrowing from MFIs.13

However, in order for the positions of IFs with euro area MFIs to be included in the money and credit aggregates of the euro area, the investment funds need to be domiciled in a Member State. In particular, this tends to reduce the direct impact of hedge funds for euro area money and credit aggregates, as they tend to be domiciled in the United Kingdom, the United States or in offshore financial centres. At the same time, transactions conducted by these foreign entities with euro area residents will be captured in the net external asset developments, and thus may be indirectly reflected in the developments of monetary aggregates.

FVCs often maintain close financial relationships with MFIs, as the latter are often the originator of the assets that FVCs securitise. It should be noted that in a traditional securitisation scheme, transactions due to MFI loan (and other asset) sales to FVCs do not generate permanent liquid financial positions. However, temporary liquid positions may arise in the period between the FVC purchase of securitised assets from MFIs and its actual cash settlement. Once the deal is settled, MFIs may purchase some (often the junior tranches) of the debt securities issued by FVCs. Moreover, FVCs may place deposits with MFIs, often on a temporary basis. Indeed, loans (and other asset) repayments are normally passed through to the end-investors as soon as they are cashed. As shown above, the estimated amount of the total balance sheet of euro area FVCs at the end of 2004 was €500 billion, three-quarters (€379 billion) of which related to the portfolio of securitised loans. At the same time, FVCs’ holdings of deposits are estimated to be around €41 billion. However, this figure may underestimate the overall magnitude, as other liquid assets held by FVCs (€9 billion) may partly reflect transactions with MFIs. Furthermore, FVCs’ holdings of securities, which may include some issued by MFIs, amount to €46 billion. On the liabilities side, the amount of short-term debt issued by FVCs and presumably held by MFIs amounts to around €1 billion. In a synthetic securitisation scheme, MFIs do not sell the loans (and other assets) to FVCs, but rather stipulate financial derivatives contracts, typically credit default swaps, to transfer credit risk. As long as the loans serving as collateral do not default, the FVC receives a premium payment from the MFI; however, in the case of a loan default, the FVC has to cover the capital losses of the MFI. This explains why

13 According to the ECB publication entitled “Large EU banks’ exposures to hedge funds” (November 2005), at the end of 2004 for a sample of 14 banks from six EU countries, cash lending to hedge funds collateralised with securities amounted, on average, to 1.5% of surveyed banks’ assets, the range being from 0% to 5.5% across countries.
FVCs’ derivatives positions may change from asset to liability rather rapidly. Importantly, FVCs issue debt securities and use the proceeds to invest in safe assets, including deposits and other financial instruments issued by MFIs.

FCLs are often financed (and owned) by MFIs, creating a double layer of intermediation which is justified by the specialisation of such intermediaries. FCLs may also finance themselves by issuing short-term commercial paper and debt securities. The available data on FCLs indicate, albeit with limitations, the importance of lending with a maturity of up to five years by MFIs to FCLs in some euro area countries.

SDDs trade securities and derivatives on their own account and risk. This trading activity may easily generate positions with MFIs, for example SDDs may invest in debt securities issued by MFIs and engage in financial derivatives transactions (sometimes leading to the creation of margin deposits) and in repurchase agreement transactions with the MFI acting as a counterparty. SDDs may also place overnight deposits with MFIs for trading purposes. In order to finance their trading activity, which tends to be of a short-term nature, loans granted to SDDs by MFIs generally have a short maturity. In some euro area countries, where SDDs play a more significant role, loans granted to SDDs can constitute a significant share of MFIs’ lending business with the OFI sector.

The typical activity of FHCs is the management of participation interests in financial corporations. This is an activity that is generally oriented towards the medium to longer term and therefore unlikely to generate sizeable short-term deposit holdings with MFIs. FHCs are generally funded through the issuance of an equity-type security.

The residual category of other OFIs may include a number of heterogeneous entities, such as venture capital companies not structured as IFs, in particular, special financial institutions, etc. The importance of this sub-sector crucially depends on the pace and nature of financial innovation. For instance, clearing houses that were traditionally pure facilitators of financial transactions may now assume a certain degree of counterparty risk in their financial services. This tendency may have implications for monetary developments, as transactions with MFIs through these clearing houses would no longer be recorded as intra-MFI transactions. To sum up, there are manifold channels through which the financial behaviour of the various business models classified as OFIs can impact MFIs’ balance sheet. From this perspective, all types of OFIs (with the possible exception of FHCs) are of interest for the analysis of monetary developments. Currently, IFs and FVCs seem to be the two sub-categories displaying the strongest interaction with MFIs, particularly with respect to developments on the liability side of the MFI balance sheet. However, the remaining sub-categories may also be relevant for monetary analysis purposes. In particular, FCLs (and to a lesser extent SDDs) may be important for monitoring overall credit developments.

Finally, looking forward, financial innovation may generate other types of OFI, which would initially be classified in the residual category. However, some of these may become important over time and contribute to structural changes both in the MFI and other OFI sub-sectors. A close monitoring of the residual category is therefore warranted.

---

14 It should be noted that while traditional clearing houses are statistically classified as Financial Auxiliaries (S.124), special entities that assume counterparty risk may need to be classified in the OFI sector (S.123).
3 THE ROLE OF OFIS IN MONETARY ANALYSIS
by B. Fischer, D. Gerdesmeier, A. Lojschova and J. von Landesberger (ECB staff)

3.1 DETERMINANTS OF OFIs’ DEMAND FOR MONEY

Money held by OFIs has become significantly more important in the analysis of monetary developments over the past decade. The euro area OFIs’ share of M3 deposits increased from around 4% in 1991 to approximately 11% in mid-2006 (see Chart 4). The rising share of non-monetary financial intermediaries’ holdings of M3 deposits has resulted in a lower share by the household sector, reflecting the growing importance of such intermediaries in households’ wealth management. At least in part, the increased importance of this sector for monetary analysis reflects financial liberalisation and innovation, as well as the associated development of deeper and more liquid securities markets.

The theory of money demand gives clear guidance on the economic motivation of households and non-financial corporations for holding liquid monetary assets. A substantial literature has investigated these motivations empirically. However, there is still no comprehensive theoretical or empirical analysis of the OFI sector, which is further compounded by the heterogeneity of its entities. In general, the literature believes OFIs’ demand for money to be driven by portfolio considerations, with the main explanatory variables being relative rates of return in the money, equity and bond markets and on real assets (such as physical capital, commodities and land). This focus on portfolio considerations typical for the literature may, however, only be appropriate for IFs and SDDs. Furthermore, the selection of appropriate opportunity cost variables to capture these influences empirically and, to a greater extent, the choice of an appropriate scale variable, remain open issues. In particular, as OFIs’ transactions demand for money is likely to be closely related to the need to settle financial transactions rather than to the purchase of goods and services. Moreover, the questions as to whether and, if so, how to incorporate measures of changes in the regulatory framework or financial structure as explanatory variables into OFIs’ money demand equations are unresolved. Against this background, defining an equilibrium level of OFIs’ money holdings and analysing how it may have changed over time remains a demanding task.

As a general point, it can be noted that OFIs’ demand for money holdings would reflect both the portfolio allocation decisions of the non-financial sector with respect to holding OFI liabilities and the portfolio allocation of the OFIs themselves. Both aspects would need to be taken into account when forming a final assessment of the nature of the recent money demand behaviour of OFIs.

3.2 THE IMPACT OF OFIs’ MONEY HOLDINGS ON THE INDICATOR PROPERTIES OF MONEY

Turning to the overall impact of euro area OFIs’ M3 deposit holdings on M3 dynamics, Chart 5 compares the annual growth rates of M3 with a measure of M3 excluding OFIs’ holdings of short-term deposits and repurchase agreements. In this regard, it should be noted that a full
exclusion of the OFI sector component of M3 is not possible, as information on the holdings by the OFI sector of currency, short-term debt securities and money market fund shares/units are not available at present. However, excluding OFIs’ holdings of short-term deposits and repurchase agreements from M3 is likely to give a fairly accurate picture of developments in M3 excluding OFIs’ money holdings in the light of the rather low demand for money market funds over the period since mid-2004. Notwithstanding the importance of OFIs’ deposit holdings for recent M3 dynamics, Chart 5 shows that, even when excluding OFI money holdings, the stylised fact of a strengthening in M3 growth since mid-2004 remains unchanged.15

At a conceptual level and to the extent that OFIs’ deposit holdings with banks mainly reflect portfolio considerations, their direct effect on future activity and prices might be negligible. Thus, insofar as portfolio shifts in and out of money dominate OFIs’ behaviour, an increasing share of OFI deposits in M3 could disrupt the indicator properties of money for future activity and prices. If OFIs’ deposit holdings were more related to asset prices developments and developments in overall private sector financial wealth, they might contain information about future activity and price developments and thus enhance the indicator properties of money with respect to those variables. Compounding these uncertainties is the extent to which recent developments in OFIs’ money demand can be seen as the result of longer-term changes in the financial market structure, rather than as a consequence of the current macroeconomic environment with low interest rates and strong asset price dynamics. Recent financial innovation and regulatory changes which substantially influence OFIs’ deposit holdings can at times also interfere with the established indicator properties of M3. Indeed, the importance of country-specific changes in financial structure and regulation can complicate the assessment of national liquidity developments but are typically seen as having a modest effect on area-wide analysis.

An analysis of recent OFIs’ money-holding behaviour in the euro area suggests that, in some specific cases, structural shifts have indeed taken place. For example, the huge expansion of repurchase agreements in OFIs’ portfolios in 2005 may point in this direction. In the case of Germany, this development appears to reflect a migration of German banks’ money market activities from direct interbank trading to an electronic trading platform for repurchase agreements that is operated by a securities clearing house and is thus part of the OFI sector. Transactions which were previously undertaken over the counter between MFIs are now conducted via this OFI-owned platform. While, in economic terms, such transactions remain an interbank business, from a statistical perspective, they now give rise to asset and liability positions with OFIs on the consolidated MFI balance sheet, including items that add to the expansion of M3. OFIs’ demand for repurchase agreements resulting from the migration to electronic trading platforms operated by OFIs should be

15 The overall trend in M3 over recent quarters has not been affected by the exclusion of OFIs’ money holdings from M3, in part because of the current strong growth rates of currency in circulation. It is assumed that OFIs are not major holders of cash.
seen as a distortion to the monetary data. Such developments (which may also be taking place, albeit on a more modest scale, in Italy) blur the indicator properties of monetary aggregates. However, the overall impact of the migration of repurchase agreement transactions to an OFI-operated platform in Germany on aggregate M3 developments is currently modest. Moreover, it is doubtful that the experience in Germany can be generalised for other countries or for the euro area as a whole.

Overall, evidence against major structural changes in OFIs’ money-holding behaviour can also be found. For example, IFs have maintained broadly similar liquidity ratios (i.e. ratio of monetary to total assets) in the euro area over recent years.

Finally, the analysis can also be extended to the components and counterparts of M3. A close link between synthetic loan securitisation by MFIs, the creation of special purpose vehicles (SPVs, classified as FVCs and thus part of the OFI sector) and OFIs’ demand for longer-term financial liabilities can be established. For example, such behaviour has been particularly important in Spain and Portugal in recent years, where regulatory changes (relating to the introduction of International Accounting Standard (IAS) 39) as well as strong mortgage market developments have played an important role in expanding securitisation. In the Netherlands, synthetic securitisations affected OFIs’ money demand, as SPVs often stored the funds raised through the issuance of debt securities as liquid deposits (that acted as collateral) and thus fuelled the growth rate of OFIs’ money holdings. The subsequent unwinding of such transactions dampened the growth rate of OFIs’ money holdings. The overall impact of synthetic loan securitisations on euro area M3 growth remains uncertain, as it is not known whether this type of activity causes substitution within M3 (without affecting euro area M3) or whether it affects euro area M3 through a change in the counterparts.

3.3 THE ROLE OF OFIS’ MONEY HOLDINGS IN ASSESSING RISKS TO FUTURE PRICE STABILITY

Are OFIs’ money holdings noise or relevant policy information? Given the predominance of such portfolio considerations in determining OFIs’ money holdings, one could wonder how to interpret monetary growth stemming from this sector when assessing the impact of monetary dynamics on inflation and output prospects. This is particularly the case since OFIs’ activities – which, by nature, are typically in the financial domain – create relatively little direct final demand for goods and services, certainly as compared with the activity of private households and non-financial corporations. Against this background, the link between OFIs’ money holdings and the medium to longer-term outlook for price stability requires specific analysis.

Preliminary findings on the information content of sectoral money developments with respect to inflation indicate that there is a closer relationship between consumer price inflation and a measure of underlying household money holdings than is the case for broader aggregate M3 or other individual sectors. However, by aggregating money holdings over different sectors to construct M3, idiosyncratic elements seem to be averaged out and substitution effects (e.g. between direct holdings of bank deposits by households and indirect holdings through IFs and other non-monetary financial intermediaries) appear to be internalised. Indeed, a broader sectoral coverage of the aggregate M3 series seems to improve the leading properties of M3 compared with the household M3 series, thereby facilitating an earlier prediction of turning points in euro area inflation.16

While OFIs’ money holdings may have a somewhat different character to those of households or non-financial corporations, their

16 See the box entitled “Sectoral money and the information content of money with respect to inflation” in the September 2006 issue of the ECB’s Monthly Bulletin.
specific contribution to overall monetary developments cannot simply be omitted when assessing risks to price stability stemming from the monetary analysis. In particular, omitting OFIs’ money holdings could mean leaving out information on financial linkages between money-holding sectors and substitution processes between asset classes, which could be relevant for price developments, especially over the medium to longer term.

3.4 THE ROLE OF OFIs IN THE TRANSMISSION MECHANISM OF MONETARY POLICY

There are basically two main reasons why monetary growth attributable to OFIs might enter the transmission mechanism of monetary policy and would thus be relevant in the assessment of the outlook for inflation and economic activity.

First, OFIs affect and/or reflect developments in the economy through their financial linkages with other sectors, to the extent that they enable firms or households to modify their spending and saving patterns. Hence, rapid growth in the total of money balances of OFIs may reflect developments in asset markets and thus private sector wealth. Increases in wealth, in turn, could lead to higher inflation via demand effects over time.

Second, excluding OFIs’ money holdings from monetary aggregates might reduce the information content of these aggregates with respect to nominal aggregate demand in the medium to longer term, the reason being that the information content of monetary aggregates rests on the fact that they subsume the complex substitution processes that occur between a large variety of assets and impact on unobservable liquidity and risk premia. These premia affect the ability of households and firms to borrow or lend, i.e. to bring forward or delay expenditure. Owing to professional risk management, OFIs may undertake transactions to provide liquidity to certain asset classes, by buying mortgage and corporate loan portfolios or factoring, for example, which are deemed too risky by non-specialised investors. To a certain extent, the recent growth in OFIs’ deposits and loans may constitute a one-off structural adjustment in the financial system. However, cyclical effects related to the low level of interest rates – inducing a desire for yield – may be reinforcing the attractiveness of certain liquidity-providing investments by OFIs. The change in the risk/return profile of the asset classes could impact on the functioning of the transmission of monetary policy via its influence on asset prices. In this regard, OFIs’ money holdings are very likely to contain relevant information over the medium to longer term that would be overlooked when analysing the money-holding sector without this group.

Turning to the analysis of the potential impact of OFIs on specific linkages of the transmission mechanism, there are a variety of channels that might, in principle, be influenced. The traditional interest rate channel is probably less vulnerable to change, as it operates largely through the consumption and investment decisions of households and firms. By contrast, an expansion of leasing and securitisation activities could lead to an increase in credit supply. This, in turn, would make bank credit less “special”, which could weaken the credit channel of monetary transmission. At the same time, by increasing the liquidity of some financial markets and acting in a pro-cyclical manner, hedge funds had tended – at least temporarily – to reduce market credit and term spreads. Finally, one can argue that if OFIs lead to an increased exposure of households to, for example, bond markets, changes in the wealth or balance sheet channel of monetary transmission could result.

At the current juncture, there is no concrete evidence regarding the influence of OFIs on the individual transmission channels. Taking differences at the country level into account, as well as the heterogeneity of the OFI sector, may help to explain the cross-country differences in the propagation of monetary policy impulses within the euro area.
4 A LOOK AT THE COUNTRY LEVEL

4.1 OVERVIEW

As shown in the previous sections, the euro area OFI sector is characterised by a strong heterogeneity with respect to the types of activity undertaken. At the same time, the relevance of OFIs for monetary developments varies considerably across countries. In part, this variation reflects the different sizes of financial markets, proxied by the relative shares of outstanding quoted shares and bonds in Table 2. A look at the relative size of the OFI sectors across the euro area indicates that OFIs resident in Luxembourg, the Netherlands and France are particularly important. However, an analysis of the distribution of M3 deposits relevant for monetary developments indicates that OFIs’ deposit holdings are more evenly spread. OFIs’ deposit holdings with MFIs resident in Germany, the Netherlands, Spain and France are among the larger holdings. Putting M3 deposits into relation with nominal GDP indicates that the OFIs in Luxembourg, Ireland and the Netherlands have large “cash ratios”.

In order to gauge the impact of the individual OFI sectors on aggregate monetary dynamics, Chart 6 shows the national contributions to the euro area annual growth in OFIs’ M3 deposit holdings. The breakdown reveals that the countries mainly “responsible” for the growth in deposit holdings have changed significantly over the last two years. Three pairs of countries can be identified. First, in 2004, the annual growth rate was primarily supported by developments in France and Spain, while in 2005 these two countries played a more ancillary role. Second, while Germany and Luxembourg played only a marginal role for most of 2004 despite their large share of money holdings in the euro area, their contribution increased substantially over the course of 2005 and early 2006. Third, for most of 2004, negative contributions from Italy and, in particular, the Netherlands were observed. However, from early 2005 onwards these contributions turned positive, and in 2006 they increased to place these countries among the larger contributors.

Overall, this breakdown indicates that the dynamics in the individual euro area countries

have diverged significantly between the beginning of 2003 and mid-2006, and therefore a deeper analysis of the individual country developments is warranted. In particular, five questions are of core interest, namely:

1. What are the main sub-sectors of the OFI sector in the individual countries and what is their relative size?

2. What have been the developments (in terms of both stocks and annual growth rates) in the OFIs’ M3 deposit holdings between 2004 and mid-2006?

3. Which economic considerations seem to drive OFIs’ demand for money (i.e. short-term deposits and repurchase agreements) in the individual countries and how do they relate to the money-holding behaviour of households and non-financial corporations?

4. How important (in terms of both stocks and developments in annual growth rates) are OFIs for the development of longer-term deposits in the individual countries? How is this related to financial innovation, such as securitisation, and regulatory changes, such as the implementation of Basel II?

5. Looking across the maturity spectrum of OFIs’ deposit holdings included and excluded from M3, what conclusions regarding OFIs’ activities can be drawn?

4.2 COUNTRY EVIDENCE

4.2.1 BELGIUM

by A. Bruggeman (National Bank van België/ Banque Nationale de Belgique)

As Belgian MFIs only report data for the OFI sector as a whole, these data cannot be used to analyse the relative importance of the main sub-sectors of the OFI sector in Belgium. However, it is possible to form an estimate on the basis of the more detailed (but not fully comparable) financial accounts data.

In terms of total deposit holdings, IFs are by far the largest sub-sector of the OFI sector in Belgium. They represented around 84% of all OFIs' deposit holdings in June 2006, while the FHCs, SDDs, the FCLs, and the other OFIs accounted for around 7%, 4%, 3%, and 2% respectively (see Chart 7).

In March 2006, the relative share of the IF sub-sector declined considerably in favour of the FCL sub-sector, most likely reflecting a large temporary flow into overnight deposits held by the latter.

Regarding the main developments, a breakdown by instrument of OFIs’ short-term deposit holdings with Belgian MFIs reveals that they have a strong preference for short-term time deposits and for overnight deposits, which over the period from 2003 to mid-2006 represented on average 73% and 22% respectively of their total short-term deposit holdings (including repurchase agreements) with Belgian MFIs.
These average figures mask the growing importance of overnight deposits, whose share rose from a low of 15% in June 2003 to almost 30% in early 2006, before decreasing to 25% in June 2006.

Disregarding the large volatility of these data, the annual growth rate of OFIs’ holdings of short-term time deposits with Belgian MFIs rose sharply in the first few months of 2004, but then fluctuated around an average of 12¾% until October 2005 (see also Chart 8). Thereafter, the annual growth rate was on a clear downward trend. The developments in the annual growth rate of OFIs’ overnight deposit holdings were quite similar up until mid-2005: after a steep rise in early 2004, they fluctuated around an average of 18½%. From then onwards, the annual growth rate was on an upward trend until March 2006, but then moderated again to even fall below the average level of the period from 2004 to mid-2005.

Between January 2003 and June 2006, OFIs’ short-term deposit holdings (including repurchase agreements) with Belgian MFIs recorded an annualised growth rate of 8%, compared with annualised rates of expansion of 8¾% for households and 10½% for non-financial corporations. However, as households are by far the largest deposit-holding sector, their average contribution to total short-term deposit holdings with Belgian MFIs was about three times higher than that of each of the other two sectors (see Chart 9).

OFIs’ strong demand for money is most likely being driven by the substantial inflows into IFs in recent years, rather than by a change in their investment strategy. According to financial accounts data up to the second quarter of 2006, the total financial assets of Belgian OFIs increased at an annualised rate of 18½% from the first quarter of 2003. These substantial inflows originated mainly from households...
and from ICPFs that had been investing a larger proportion of their total financial assets in mutual fund shares. Belgian households’ holdings of mutual fund shares grew at an annualised rate of 12½% from the first quarter of 2003 (while their total financial assets rose by 6¼%). Similarly, Belgian ICPFs increased their holdings of mutual fund shares at an annualised rate of 15¾% (compared with 14½% for their total financial assets).

Belgian OFIs’ demand for money would have been even higher in recent years had they not reduced the proportion of deposits in their total financial assets, from 17% in 2003 to 12% in the second quarter of 2006. The apparent lower liquidity preference of Belgian OFIs could reflect their reduced liquidity needs to cover potential withdrawals of funds, given the large inflows that they had received. At the same time, it could also reflect a change in the investment strategy of both investors in mutual funds and of IFs themselves in a context of reduced risk aversion and the desire for yield in an environment of persistently low interest rates.

Longer-term deposits with Belgian MFIs are mainly held by OFIs (see Chart 10). During the last three and a half years of the period under review, their share gradually increased from 86% in January 2003 to 93% in June 2006, at the expense of households’ holdings of longer-term deposits. To some extent, this was a result of the fact that the annual growth rate of households’ holdings of longer-term deposits had been consistently negative over the period under review. At the same time, OFIs’ holdings of longer-term deposits with Belgian MFIs accelerated towards the end of the period under review, growing at an annualised rate of 23¾% between December 2005 and June 2006, compared with an annualised rate of expansion of 15¾% between January 2003 and December 2005.

A closer look at the maturity spectrum reveals that OFIs’ deposit holdings with Belgian MFIs mainly took the form of short-term time deposits (43%), longer-term (time) deposits (42%) and overnight deposits (13%), although their preference for longer-term (time) deposits seemed to increase recently. This distribution
suggests that OFIs’ holdings of deposits with Belgian MFIs are used both for investment purposes and for transaction purposes.

To sum up, developments in Belgian OFIs’ deposit holdings reflect a reduction in their share in OFIs’ total financial assets, which in turn grew vigorously in recent years. The impact of OFIs on developments in total deposit holdings with Belgian MFIs is particularly important for the longer-term deposits that are not included in M3. For the short-term deposits included in M3, the impact has generally been limited until now, in the sense that excluding OFIs’ short-term deposit holdings from M3 would not change the pattern of the Belgian contribution to euro area M3 growth significantly.

4.2.2 GERMANY
by J. Reischle (Deutsche Bundesbank)

The OFI sector in Germany is dominated by IFs (excluding money market funds). IFs deposits and repurchase agreements with German banks account for around three-quarters of all the German OFI sector’s deposits and repurchase agreement transactions with domestic banks (see Chart 11). The fact that the residual category of other OFIs still accounts for almost one quarter of bank deposits and repurchase agreement transactions is mainly because this sub-sector also includes a big German securities trading house, the subsidiary of which – a distinguished German custodian – provides a trading and clearing platform for repurchase agreement transactions, which is used by some German banks for secure money market trading. Since the custodian has attracted a greater trading volume since the beginning of 2005, and because it acts as the central counterparty in such transactions, both domestic banks’ repurchase agreement transactions with and short-term bank loans to this OFI (see Chart 12) have increased markedly.

With regard to short-term deposits held by German OFIs with German domestic banks, overnight deposits account for the largest share, which, in June 2006, constituted about two-thirds of the short-term deposits and repurchase agreement transactions of German OFIs. The domestic OFI sector also holds short-term time

deposits, but with a share of only 6%, these are relatively unimportant. Furthermore, from the beginning of 2005 onwards repurchase agreement transactions by German OFIs with domestic banks also played an important role. However, since these transactions are mainly money market transactions between banks, they do not involve a net inflow of funds to the private non-banking sector. In addition to domestic OFIs’ deposit holdings, OFIs domiciled in other euro-area countries hold short-term deposits and carry out repo transactions. Compared with domestic OFIs’ holdings, however, foreign OFIs’ holdings are low.

As IFs are of paramount significance for the OFI sector in Germany, the short-term deposits of this sub-sector (excluding repurchase agreement transactions) are likely to reflect, in particular, its liquidity requirements. While the money holdings feed on the inflow of capital from the sale of IF certificates, they are at the same time needed for the redemption of these fund certificates, which can occur at any time. According to the statistics concerning IFs in Germany, open-end real estate funds in Germany held 11% of their fund assets as bank deposits in June 2006. Standing at 5%, the corresponding share for securities-based funds was only half as large. This percentage matched the legal requirement exactly. Owing to their large fund assets, the domestic securities-based specialised funds accounted for the largest amount – €30 billion – of the bank deposits held by German IFs. Fund managers state that liquidity reserves are one of the most important risk management tools in investment activity. In addition to the increased performance pressure on German securities-based funds, the interest rate level and the situation on the financial and real estate markets, in particular, are likely to influence the liquidity holdings of IFs.

When considering the deposits and repurchase agreement transactions of German OFIs across the maturity spectrum, a marked increase in short-term deposits (including repurchase agreements) becomes evident. Overnight deposit holdings, short-term time and savings deposits as well as repurchase agreement transactions – which have only a short maturity – increased sharply from the beginning of 2003 onwards (by €40 billion, or 68%). The short-term deposit holdings of OFIs domiciled in other euro area countries also increased strongly (by €13 billion, or 184%). By contrast, long-term time and savings deposits of OFIs in the euro area fell by a quarter (or €13 billion) over the same period. In spite of the more pronounced short-term orientation of OFIs, their overall bank deposits ultimately expanded only a little more than the bank deposits of the other money-holding sectors. Consequently, the share of OFIs’ holdings increased only slightly, from 6% at the beginning of 2003 to 6.8% in June 2006.

All in all, the deposits held by euro area OFIs at banks in Germany are clearly dominated by IFs. This notwithstanding, owing to repurchase
agreement transactions between a large German custodian and domestic credit institutions, the German OFI sector at times had a notable impact on the monetary dynamics in Germany, namely in 2005 and early 2006. However, on balance the OFI sector resident in Germany as well as in other euro area countries is virtually of no relevance to monetary developments in Germany. In spite of a somewhat stronger underlying trend, OFIs’ short-term bank deposits (with and without repurchase agreement transactions) are, for the most part, developing in parallel with the M3 deposits held by the euro area private sector with German MFIs, particularly households’ deposits.

4.2.3 IRELAND
by M. Cussen, D. Doran & R. Mottiar (Central Bank and Financial Services Authority of Ireland)

OFIs in Ireland have grown sharply over the last decade so that they now account for a substantial proportion of the financial system. Estimates indicate that Irish OFIs’ balance sheet totals increased from around €360 billion in 2000 to around €870 billion in March 2006. OFIs themselves are a rather heterogeneous group of institutions which, in an Irish context, can be broken down into three broad types of entity:

1. IFs: Also referred to as collective investment schemes. At the end of 2005, there were approximately 3,890 funds in this sub-sector in Ireland, constituting approximately 47% of OFIs’ total holdings in Ireland in March 2006. A large proportion of the IFs are issued in non-euro currencies and a breakdown of their assets and liabilities indicates that they predominantly hold and issue securities and equity. These IFs are traded predominantly with the rest of the world and, as such, are largely vehicles enabling non-residents to invest and have little direct relationship with the domestic banking system.

2. Stand-alone treasuries: this OFI sub-sector includes three different vehicles for treasury operations; namely stand-alone treasury companies, agency treasury centres and captive finance companies. In March 2006 this sub-sector accounted for approximately 16% of OFIs’ total holdings in Ireland. Similar to the IF sector, the international trading nature of these entities means that they have little direct relationship with the domestic banking system.

3. Miscellaneous international trading companies: this OFI sub-sector in Ireland is quite significant and growing, accounting for approximately 37% of OFIs’ total holdings in March 2006. This sub-sector includes specialist debt/financing entities that specialise in securitisation, as well as leasing companies, asset management companies, securities trading companies, and agency and captive treasury companies (see Chart 13).

The annual growth rate of short-term deposits and repurchase agreements in Ireland rose steadily from 2004 onwards, reaching approximately 30% by mid-2006 (see Chart 14). Much of this annual growth rate was attributable to the increased contribution of overnight deposits and, towards the end of the period under review, to

Chart 13 OFIs’ holdings by sector
(percentages, March 2006)

- miscellaneous international trading: 37.1%
- investment funds: 46.6%
- standalone treasuries: 16.3%

Source: Central Bank and Financial Services Authority of Ireland.
the strengthening contribution of deposits with an agreed maturity of up to two years. However, the impact of the strong annual growth rate of short-term deposits was somewhat diluted by the negative growth rate of repurchase agreements from December 2005 onwards.

From 2004 onwards during the period under review, there was a strong increase in the annual growth rate of short-term deposits and repurchase agreements in Ireland. While the OFI sector experienced strong annual growth rates during this period, the household and non-financial corporation sectors recorded similar growth rates (see Chart 15). Consequently, there was no significant change in OFIs’ short-term deposit holdings and repurchase agreements as a percentage of total short-term deposits and repurchase agreements. While low interest rates and opportunity costs led the household and non-financial corporation sectors to engage in portfolio shifts from longer-term and riskier investments to short-term deposits towards the end of the period, evidence suggests that the OFI sector did not necessarily engage in such portfolio shifts. Generally, the growth in OFIs’ deposit holdings seems to be related to the growth in different asset classes.

The annual growth rate of longer-term deposits in Ireland declined from approximately 30% in January 2004 to approximately 15% by mid-2006 (see Chart 16). Much of this decline was the result of the declining annual growth rate of longer-term deposits made by households, whose contribution to annual growth in longer-term deposits fell from 17.8 percentage points to 5.7 percentage points during the same period. While the contribution of OFIs to longer-term deposit annual growth fluctuated during the period, its trend contribution did not change significantly. SPVs constitute a significant proportion of the OFIs in Ireland. Quite a large number of euro area securitisation transactions, from mortgage-backed securities to collateralised debt obligations, are issued through SPVs in Ireland, with the result that the cash flow from securitisations to these entities is quite large and disproportionate to the level of activity in Ireland.
Looking across the maturity spectrum of OFIs’ deposit holdings included and excluded from M3, evidence suggests that the growth in these deposit holdings was the result of an increase in OFIs’ investment volume and not necessarily the result of OFIs shifting from longer-term and riskier assets to shorter-term investments. An analysis of OFIs’ deposit holdings by duration as a proportion of total deposit holdings indicates that OFIs’ deposit holdings in each duration, both those included in and excluded from M3, grew in similar proportions in relation to total deposit holdings. This indicates that OFIs apportioned funds across deposit categories in a uniform manner and did not increase the number of short-term deposits at the expense of longer-term deposits. OFIs in Ireland, in the aggregate, apportioned funds across deposit durations according to a pre-defined investment strategy, as no single deposit duration category became more important relative to total deposit holdings over the period. An analysis of the growth rates of OFIs’ different assets classes adds further support to this observation, as similar growth rates were experienced across asset classes. This also suggests that OFIs did not switch from riskier assets to safer short-term deposits.

The Irish economy has expanded at substantial annual growth rates over the last decade. This rapid growth has been accompanied by a significant increase in the size of both bank and non-bank intermediaries. While the main channel for intermediation remains the banks, which comprise large domestic credit institutions conducting business mainly with residents and other domestic banks, and branches and subsidiaries of foreign banks with mainly non-domestic business, non-bank intermediation is also an important channel through which funds are intermediated.

Within this category, OFIs have grown sharply in the last decade and now account for a substantial proportion of the financial system in Ireland. A friendly and supportive economic environment, including favourable corporation tax rates, remains one of the key reasons for the establishment of a wide range of financial services in Ireland.

4.2.4 FRANCE
by E. Fonteny & S. Frappa (Banque de France)

In France, the main OFI sub-sector is IFs, which make up 72.4% of the balance sheet of the OFI sector (i.e. €1,083 billion in June 2006). French IFs account for 20% of the total activity of euro area IFs. The second most important sub-sector includes SDDs (around 160 “investment firms”) and accounts for 23.1% of the total balance sheet OFIs (i.e. €346 billion). The third sub-sector refers to FCLs, which include specific institutions financing social housing through contributions from firms (“Comités interprofessionnels du logement”) or motorways (“Caisse Nationale des Autoroutes”). These institutions account for 3% of OFIs’ total balance sheet. The last sub-sector consists of FVCs, which make up 1.4% of OFIs’ total balance sheet (see Chart 17).

Developments in OFIs’ short-term deposit holdings included in M3 reflect strong growth in
overnight deposits and deposits with an agreed maturity of up to two years, while the annual growth rate of repurchase agreements decreased somewhat from January 2004 onwards during the period under review. In fact, the annual growth rate of overnight deposits reached 69% in June 2006, a level fairly close to the highs recorded at the beginning of 2004 (73% in June 2004 for instance). Deposits with an agreed maturity of up to two years grew by 31% in June 2006, whereas their annual rate of change had been almost continuously negative up to mid-2005. Conversely, repurchase agreements held by OFIs recorded a sharp decline from December 2005 onwards, falling by 20% in June 2006, as opposed to a year-on-year increase of 42% in June 2004.

To gain a better understanding of developments in OFIs’ deposit holdings, one may also refer to the dynamics of their contributions to the annual growth rate of short-term deposits (see Chart 18). In this context, the contribution of overnight deposits reached 19 percentage points in June 2006 from 11.7 percentage points in June 2004. Conversely, the contribution of repurchase agreements decreased from 24.8 percentage points in June 2004 to -12.7 percentage points in June 2006 (see Chart 19).

Moreover, holdings of money market fund shares by general purpose IFs have shown positive trends during the last two years of the period under review. The average annual growth rate between the end of 2003 and the end of 2005 was 14.7%.

The two main sub-sectors within the French OFI sector are IFs and SDDs. OFIs’ deposit holdings probably reflect two types of financial behaviour. On the one hand, IFs’ deposit holdings originate from the management of liquidity risk by fund managers, as most IFs are legally required to maintain the liquidity of their unit shares. In this regard, it is noticeable that the share of liquid assets, such as money market funds, in the portfolio of IFs is fairly stable.17 Mutatis mutandis, an increase in IFs’ assets following, for instance, a rise in stock

---

17 Regarding general purpose investment funds, the weight of money market funds in their net asset value, after excluding funds of funds, amounted to 3.46% between mid-1999 and mid-2006, with a standard deviation of 0.02 percentage point.
prices, could entail an almost equivalent rise in IFs’ liquidity reserves.

On the other hand, households’ subscriptions to IFs, either directly or indirectly through life insurance contracts, tend to lower their liquidity ratio, measured for instance by the “transferable deposits to total financial assets” ratio in the case of households or by the “transferable deposits to balance sheet total” ratio in the case of mutual funds, as was the case to some extent from March 2005 onwards. More generally, the economic considerations driving OFIs’ demand for money are quite different from those that may explain the demand for money by non-financial agents and more particularly by households. In this regard, the calculation of a liquidity ratio in both cases (transferable deposits compared with total financial assets for households, or with balance sheet total for IFs) shows that the amount of liquidity compared with total assets is larger for households than for mutual funds, reaching 3.8% in the case of IFs and 26.5% in the case of households (as of March 2006). More precisely, the liquidity ratio of households decreased somewhat from March 2005 onwards, whereas the weight of life insurance contracts and mutual funds shares in the total financial assets of households was firmly on the rise.

Turning to SDDs these are subject to the same prudential regulation as credit institutions as far as their market activities are concerned. Moreover, they are very often subsidiaries of credit institutions. They could therefore be deemed to manage their liquidity constraint in the same way as banks. Further, they normally use repurchase agreements as a means of securing their borrowing/lending of cash/securities. Their activities and demand for money therefore have more repercussions on banks than on non-financial agents.

Over the period January 2004 to January 2006, OFIs’ contribution to the developments in longer-term deposits in France was quite negligible (see Chart 20). Thereafter, however, this contribution increased to such an extent that it hit its highest level of 2.6 percentage points in June 2006. This development was probably linked to the change in the tax treatment of housing saving schemes (“Plan...
d’Epargne Logement”) that came into force at the beginning of 2006. In response to this change, which reduced tax incentives on these schemes, households shifted part of their holdings from this instrument to life insurance contracts, money market funds or IFs. However, IFs could have reinvested this flow of new resources in longer-term deposits. The impact of securitisation on longer-term deposits remains negligible in France.

OFIs’ deposit holdings are mainly composed of short-term instruments included in M3 (80% in July 2006) but also to a lesser extent, of long-term deposits (20% in July 2006). Repurchase agreements account for 52%, overnight deposits for 33% and deposits with an agreed maturity of less than two years for 15% of the total holdings of short-term deposits and repurchase agreements. This maturity distribution reflects the behaviour of the two main sub-sectors previously mentioned: IFs, which favour short-term deposits for investment purposes but also to ensure the liquidity of their shares, and SDDs, which favour repurchase agreements.

Taken together, IFs in France developed steadily during the period under review. From September 2003, the annual growth rate of their aggregated balance sheet was continuously higher than 10%. These developments may have been linked to several tax and regulatory changes. For example, as mentioned before, the recent reduction in tax incentives on housing saving schemes induced, inter alia, a shift in savings from these schemes to mutual funds, which, in turn, may have partly reinvested this flow in short-term deposits and money market fund shares.

**4.2.5 GREECE**

by Th. Vlassopoulos (Bank of Greece)

In terms of holdings of liquid assets (cash, deposits, repurchase agreements and bank bonds) the OFIs sector in Greece is dominated by IFs, which command more than two-thirds of the sector’s total holdings. Within this sub-sector, open-ended IFs are by far the largest holders of liquid assets, while closed-end funds hold less than 3% of the sub-sector’s total holdings. SDDs are the second largest sub-sector, closely followed by the residual category of other OFIs, which, in the case of Greece, comprises almost exclusively FHCs. FCLs make a small contribution to OFIs’ total holdings of liquid assets, as their relationship with MFIs is reflected mainly on the liabilities side of their balance sheets. There are no FVCs based in Greece (see Chart 21).

Repurchase agreements were the dominant instrument within OFIs’ holdings of short-term deposits and repurchase agreements at the start of the period under review, representing approximately 80% of the total in January 2004. However, this share declined as OFIs replaced their holdings of repurchase agreements with overnight deposits and deposits with an agreed maturity. This process was greatly expedited by the introduction, in January 2005, of a harmonised tax rate of 10% on the returns of deposits (previously 15%) and of repurchase agreements (previously 7%). Owing to this change, deposits with an agreed maturity of up to two years exhibited very high growth rates, as they attracted funds not only from
placements in repurchase agreements but also from the longer-term side of the maturity spectrum (see Chart 22). Consequently, at the end of the period under review, deposits with an agreed maturity of up to two years had become the most prominent short-term instrument for OFIs, accounting for a share of approximately 40% in this category. Throughout the period under review, deposits redeemable at notice of up to three months held a negligible share.

Given that the overwhelming majority of monetary assets in the OFI sector in Greece are held by IFs, their decisions regarding the amount of monetary assets to hold, by and large, define the money-holding behaviour of the sector. Hence, portfolio considerations, i.e. the relative returns on various assets, are the main driver of OFIs’ demand for money in Greece. Moreover, some of the investment strategies pursued by IFs, such as positions in derivatives, necessitate the holding of liquid assets in order to cover margin calls, for example. Finally, open-ended IFs in particular, need to hold a portion of their assets in liquid form in order to be able to repay share/unit holders as required.

These considerations suggest that movements of household portfolios out of money and into IFs will be followed by an increase in OFIs’ money holdings, albeit of a lesser magnitude.

The level of OFIs’ longer-term deposits remains very low in Greece, amounting to approximately 3% of total longer-term deposits in July 2006. This observation notwithstanding, the contribution of OFIs to the overall developments of longer-term deposits was higher from July 2005 onwards, when the large increase in OFIs’ holdings of such deposits was in line with the rapid growth in the new type of IF, the “fund of funds”. Nevertheless, this effect is expected to be merely transitory. The various mortgage and consumer loan securitisation transactions that took place in Greece from the end of 2003 did not impact OFIs’ longer-term deposit holdings, as the FVCs through which these securitisations were carried out are based overseas. Furthermore, the implementation of Basel II did not have a marked effect on OFIs’ longer-term deposit holdings during the period under review.

The overall importance of OFIs’ deposit holdings in Greece remains low compared with other sectors, as OFIs hold slightly more than 1% of the total deposit holdings. This reflects the fact that OFIs’ portfolios are dominated by other types of asset, such as shares and bonds in the case of IFs, or loans in the case of FCLs. Moreover, the small contribution of OFIs’ deposit holdings compared with the euro area average, to some extent reflects the lesser importance of IFs in Greece, as well as the absence of some money-holding institutions that are classified as OFIs, such as hedge funds, clearing houses that assume a certain amount of counterparty risk and FVCs.

As a general assessment, developments in OFIs’ money holdings do not seem to have had a significant bearing on the Greek contribution to euro area M3. Moreover, there are at present no indications that the importance of the OFI sector on Greek monetary developments is increasing.
4.2.6 ITALY
by G. Ferrero & A. Nobili (Banca d’Italia)

In terms of total financial asset holdings, IFs are by far the largest OFI sub-sector in Italy. Calculated from balance sheet data, open-ended IFs represented around 69% of all OFIs’ financial asset holdings in March 2006. FCLs are the second largest sub-sector, representing around 31% of OFIs’ total financial assets. SDDs, which refer to SIMs (Società d’intermediazione mobiliare) and the residual category of other OFIs accounted for only around 0.3% (see Chart 23). In terms of total deposit holdings, IFs constituted 96% of OFIs’ total holdings, the remaining 4% being held by SIMs. FCLs, on the other hand, made a negligible contribution to OFIs’ total liquid asset holdings, as their relationship with MFIs is mainly reflected on the liabilities side of their balance sheet. There are no balance sheet data available for total deposits held by the residual category of other OFIs.

Between January 2004 and mid-2006 the patterns of OFIs’ short-term deposits and repurchase agreements included in M3 were characterised by two different phases. They experienced a significant contraction up to November 2004 and then accelerated considerably in the subsequent period (see Chart 24). The pattern over time of the implied annual growth rates was rather volatile. Among the different instruments, these developments mainly mirrored the pattern of the individual contribution of repurchase agreements to the overall growth rate of deposits, and, to a small extent, that of overnight deposits.

In Italy, OFIs hold money primarily for speculative purposes, as they distribute their total financial assets among risky assets and liquidity. Consequently, their demand for money is largely driven by portfolio considerations and is expected to depend on the relative rates of return in the money, equity and bond markets and on real assets, as well as volatility in financial markets. OFIs’ demand for money basically reflects IFs’ money holdings, which manage long-term private savings. Higher money balances are usually held as a buffer to allow for unpredictable shifts in the flow of...
funds and are likely to be spent on purchasing assets, leading to upward pressure on asset prices and generating wealth in the economy. OFIs’ money holdings are therefore likely to influence households’ demand for money to a large extent through a positive wealth effect. Shifts in the deposit holdings of SIMs are likely to largely reflect short-term speculative positions, which should have little influence on households’ demand for money. Chart 25 documents the developments in short-term deposits and repurchase agreements.

In Italy, overall longer-term deposits strongly decelerated during the first quarter of 2004, continuing to fall considerably until March 2005, which mainly reflected developments in the money holdings held by households. Subsequently, they started to accelerate considerably, the annual growth rate peaking at 61% in March 2006. OFIs played a crucial role in these developments, as their individual contribution basically explained the overall increase in the growth rate of total longer-term deposit holdings (see Chart 26).

Looking at the maturity spectrum, it should be noted that, given the fact that a significant part of the overall increase in OFIs’ total deposit holdings was driven by longer-term deposits, the effect of the inclusion of short-term deposits and repurchase agreements held by OFIs in Italy’s contribution to the growth rate of M3 should be small.

One way to derive policy implications from OFIs’ money holdings is to assess whether their pattern over time reflected a decrease in their degree of liquidity or a reduction in their size in the economy, thus reflecting permanent changes in the financial structure. Looking at the balance sheet data regarding Italian open-end investment funds, a 35% decrease in total deposits (including those not included in M3) during the period under review can be noticed, in contrast with a 5% increase in total financial assets. Overall, the degree of liquidity of IFs, measured by the ratio of total deposits to total financial assets remained, on average, close to its mean value (7%) for the period 1998-2006. The basic explanation stems from Italian commercial banks’ supply strategies, which aim to sell customers IFs operated by
management companies that they themselves have set up in foreign financial centres (e.g. Ireland and Luxembourg). In addition, the decrease in Italian management companies’ share is a result of the supply strategies of the largest banking groups, which, in recent years, have steered customers towards products other than IFs, such as insurance policies and bank bonds.

4.2.7 LUXEMBOURG
by P. Lünnemann (Banque centrale du Luxembourg)

Currently, the Luxembourg OFI statistics cover two reporting categories of OFI sub-sectors, i.e. IFs (other than money-market funds) and SDDs. The total assets of these reporting units were roughly €1.6 trillion in the first quarter of 2006, thereby exceeding the total assets of MFI s by around 56%. Besides these categories of reporting units, the Luxembourg financial centre distinguishes other types of financial intermediaries, which enter the monetary statistics as counterparty. According to supervisory sources, in the first quarter of 2006, the total balance sheet of “professionals of the financial sector” classified as OFIs was €57 billion, more than 90% of which related to financial corporations engaged in lending, roughly 3.5% to professionals engaged in credit offering and almost 1.5% to professional custodians of securities. 18 Finally, in March 2006, a total of 54 “investment companies in risk capital” and 7 securitisation vehicles were recorded, the size of which is unknown (see Chart 27). 19

Between 2004 and mid-2006, the Luxembourg financial centre witnessed a very heterogeneous development in short-term deposits and repurchase agreements included in M3. In 2004, the average annual growth rate of short-term deposits and repurchase agreements was 1.7%, well below the average 8.3% and 11.0% recorded in 2005 and in the first half of 2006 respectively. Among the group of short-term deposits and repurchase agreements included, again, the developments have been quite diverse. Whereas the volume of deposit holdings redeemable at notice more than doubled between the first half of 2003 and the first half of 2006, deposit holdings with an agreed maturity of up to two years hardly changed. While the holdings of overnight deposits and of deposits redeemable at notice up to three months accelerated in late 2004, deposits with an agreed maturity of up to two years actually declined in the first half of 2005. More recently, stronger dynamics in deposits with an agreed maturity of up to two years coincided with a moderation in the developments in overnight deposits. The largest contribution to the growth of deposits included in M3 can be attributed to the sound

---

18 In addition, by the end of 2006Q1, the Luxembourg financial centre distinguished 169 "professionals of the financial sector engaged in activities connected to or complementary to the financial sector" (aggregate balance sheet: € 3.2 billion), which are not considered to be part of the Luxembourg OFI population.

19 Owing to double counting, however, it cannot be ruled out that the figures for OFIs other than IFs and SDDs are biased upwards.
growth in overnight deposits in both 2004 and 2005: this is compounded by the significant share of overnight deposits in overall short-term deposits and repurchase agreements. In total, overnight deposits contributed approximately 10 percentage points to the cumulated growth of deposits included in M3 recorded between 2003 and mid-2006 (approximately 15%), deposits redeemable at notice up to three months and deposits with an agreed maturity of up to one year contributed another cumulated 3.6 and 1.5 percentage points, respectively. Deposits with an agreed maturity of between one and two years and repurchase agreements, by contrast, hardly affected the dynamics in short-term deposits and repurchase agreements (roughly 0.1 percentage points cumulated).

Contrary to the situation at the euro area level, where OFIs account for just over 10% of total short-term deposits and repurchase agreements, in Luxembourg they account for almost 50% of the deposits in M3. Similar to the euro area, OFI holdings contributed substantially to the cumulated growth in short-term deposits and repurchase agreements included in M3 recorded over the three and a half years of the period under review. In general, the OFI holdings reveal a very limited correlation with the traditional money-holding sectors. The reasons for this may be manifold: first, OFI money holdings may depend on fundamentals other than determinants of money-holding behaviour among households and non-financial corporations, even though common money demand determinants may extend to OFIs. For example, similar to non-financial corporations, the rising interest rate expectations might have increased OFIs’ demand for time deposits. However, narrative evidence suggests that OFIs are responsive to differences in national legislation. Anecdotal evidence suggests that the explanatory variables of OFI money demand may relate to group-specific cash management activities and treasury management operations not necessarily linked to the fundamentals of the Luxembourg and/or the European economy. This is of particular importance for Luxembourg considering that a large share of deposits is not actually held by domestic residents. Moreover, OFI money demand is generally considered to be driven by portfolio considerations and the money-holding behaviour of OFIs is more volatile than the money-holding behaviour of households. By contrast, OFI behaviour is not necessarily more volatile than that of non-financial corporations, insurance companies and pension funds. Contrary to other money-holding sectors, OFIs tend to invest relatively more in assets denominated in currencies other than the euro (e.g. in the case of overnight deposits, roughly 40% for OFIs against less than 10% for private households). Differences across money-holding sectors not only apply to the share of non-euro deposits, but also to the developments therein, which might suggest a more important role as regards international developments, exchange rates, etc. for OFIs. Second, whereas some of the determinants of money holding may be identical, OFIs may react to changes in determinants in a way different from households and non-financial corporations. Third, the OFI sector is still expanding, more so than other private money-holding sectors. Moreover, banks might have outsourced activities (e.g. trading) to their group-specific investment firm. Whereas from June 2003 to June 2006 the total assets of Luxembourg MFIs increased by less than 25%, the total assets of OFIs more than doubled. Fourth, OFI money demand behaviour itself may have been subject to changes. The fact that the share of short-term deposits and repurchase agreements to total assets diminished by roughly one third over the last three years of the period under review might indicate a change in OFI money demand. A distinction between money demand by residents on the one hand and money demand from other euro area Member States can only attenuate the divergences observed. To sum up, the determinants of OFI money-holding behaviour in Luxembourg are less clear than for traditional money holding sectors. Moreover, contrary to the case of private households, restricting the analysis to OFIs resident in Luxembourg is unlikely to provide a strong link between money demand and the fundamentals of the national economy, as “domestic” OFIs’ clients are only partly domestic, they mainly reside abroad.
OFIs have been the single most important driver for the growth in longer-term deposits. More recently, however, growth has been driven by non-financial corporations while the contribution to growth from OFIs has declined somewhat and even turned slightly negative in June 2006. The dynamic expansion of longer-term OFI deposits (before the recent slowdown) relative to other money-holding sectors entailed a major sectoral reallocation: in early 2003, OFIs held just over 10% of total longer-term deposits; by mid-2006, this share reached over 50%. On the basis of currently available data, it is impossible to conclude whether this is linked to a rise in securitisation activity. Although the new law of March 2004 establishes a legal framework for securitisation vehicles, there is no published data on the volume of securitisation activity in Luxembourg. Even if there were data on the business activity of the 12 securitisation vehicles registered under the new law by the end of February 2007, it would still not be possible to give an unbiased account of securitisation activity as there could potentially be a large number of unregistered FVCs. 20

Total deposits held by OFIs have increased across virtually the entire maturity spectrum since 2003; however, there are considerable variations across instruments. In particular, although short-term deposits including repurchase agreements held by OFIs have increased significantly, longer-term deposits not included in M3 have risen exponentially in comparison. The dynamic expansion in longer-term deposits is almost entirely attributable to a steep rise in deposits with an agreed maturity of over two years, as OFI holdings of deposits redeemable at notice over three months are virtually non-existent in comparison. As for the evolution of short-term deposits, OFI holdings remain largely concentrated in overnight deposits, which now make up almost half of all short-term deposits held by OFIs, as well as in deposits with an agreed maturity of up to two years. Repurchase agreements held by OFIs remain insignificant compared with other short-term instruments.

4.2.8 NETHERLANDS
by M. Hendrikx & M. de Jong (De Nederlandsche Bank)

In the Netherlands, FCLs represent the largest OFI sub-sector. Rough approximations indicate that about half of OFIs’ deposits and three-quarters of the loans to OFIs made by MFIs are held by FCLs. This sub-sector is a mixture of financing corporations, mail-order firms that extend consumer credit, public credit institutions, real estate financing funds and development agencies. Around a third of OFIs’ deposits with MFIs are held by SPVs, mainly related to the rapid increase in the securitisation of bank loans. IFs are a relatively small sub-sector in the Netherlands. This is a result of large pension savings, which reduces the demand for IFs. Around 18% could not be classified (see Chart 28).

From mid-2005 onwards, OFIs’ short-term deposits contributed substantially (approximately

20 It is not possible to tackle this issue using information reported under Regulation ECB/2001/13 as MFIs are not required to indicate whether or not the loans on their balance sheets have been securitised.
As regards the factors driving OFIs’ demand for money, FCLs’ demand for money is likely to be related to lending and borrowing developments in the private sector, and is thus connected to the business cycle. In addition, FCLs’ demand for money may reflect financial innovation in the Netherlands, which has stimulated the growth of the financial services sector.

Turning to SPVs, the demand for money seems to be driven primarily by synthetic securitisations. SPVs usually hold short-term deposits as collateral for the asset-backed securities that are issued to finance synthetic securitisations. The growth rate of OFIs’ short-term deposit holdings is therefore affected by synthetic securitisations undertaken by MFIs. In the Netherlands, a number of factors contributed to the strong growth in securitisation in recent years. First, the volume of outstanding mortgages grew rapidly over the last decade, in part owing to the strong housing market developments. Second, the Dutch banking sector is characterised by a few large banks that can securitise large pools of loans at once, thus allowing banks to perform securitisations in a cost-effective way. Third, the new regulation that was introduced in 2004 facilitated securitisation growth, as banks are no longer required to inform debtors about the securitisation of the loan (so-called collateral for the asset-backed securities).
silent cession). More generally, securitisation was also stimulated by the very low interest rate environment and improvements in asset-liability management.

The impact of synthetic securitisations on total M3 growth in the Netherlands depends on (offsetting) movements in other money-holding sectors. Anecdotal information suggests that securitisations by Dutch banks are predominantly funded by Dutch investor counterparties, often through subsidiary offices in Luxembourg. Approximately 10% of the funding for SPVs comes from counterparties outside the euro area (usually the United Kingdom). Consequently, Dutch securitisations may have only a limited impact on the net external assets of the euro area.

As regards the growth rate of longer-term deposits in the Netherlands, OFIs were the dominant driver in recent years (see Chart 31). In 2005, for instance, the strong growth in longer-term deposits was driven almost exclusively by OFIs. The growth in OFIs’ longer-term deposit holdings can be related to specific financial transactions between MFIs and OFIs (not necessarily SPVs).

OFIs’ demand for longer-term deposits is determined partly by the duration of the financial transactions. Synthetic securitisations are more likely to impact OFIs’ longer-term deposit holdings when the lifespan of the transaction is longer.

In terms of Basel II, the impact on total securitisation activity seems to be mixed. As regulatory requirements are sharpened, synthetic securitisations may become less attractive, as they may no longer be used to improve the capital adequacy ratio. However, this could in turn boost true-sale securitisations. More generally, securitisation activity is expected to increase further owing to the increasing importance of risk management and asset/liability management by banks.

To sum up, as far as the deposit holdings of Dutch OFIs are concerned, the demand originates mainly from FCLs and SPVs. In particular, synthetic securitisations may affect OFIs’ demand for short-term deposits. With regard to longer-term deposits, the demand seems to be strongly influenced by specific financial transactions that are not necessarily related to macroeconomic developments.

The OFI sector has become increasingly important as a money-holding sector in the Netherlands. Developments in FCLs are likely to be associated with the business cycle, but financial innovation may also play a role. The FCL sub-sector therefore deserves more detailed analysis. The size of the second largest sub-sector, SPVs, is expected to continue to increase owing to the popularity of securitisation. So far, synthetic securitisations have mostly influenced OFIs’ short-term deposit holdings. However, a rise in interest rates or new financial regulations associated with Basel II or the International Financial Reporting Standard (IFRS) may alter the impact of securitisation on OFIs’ demand for deposits.
4.2.9 AUSTRIA

by Ch. Beer (Oesterreichische Nationalbank)

IFs are by far the largest OFI sub-sector in Austria, accounting for more than 99% of OFIs’ total assets.\textsuperscript{21} By the end of the first quarter of 2006, the 27 capital investment companies in Austria were offering 2,126 investment funds in which a total of €164.4 billion (€156.2 billion at the end of the second quarter of 2006) was invested.\textsuperscript{22} The preponderance of universal banks may help to explain the minor importance of OFIs other than IFs. Institutions that are legally entitled to collect deposits are not regarded as part of the OFI sector, even if their activities closely resemble those of OFIs and they do not collect deposits. Consequently, the other OFI sub-sectors play a negligible role, as they account for less than 1% of OFIs’ total assets (see Chart 32).

From 2004 to mid-2006 short-term deposits and repurchase agreements of the private sector in Austria grew by 3.5% to around 9% (see Chart 33). Growth accelerated at the beginning of 2005 and remained above 6% thereafter. Prior to 2005 growth in short-term deposits was driven mainly by households. As of 2005 non-financial corporations and OFIs started to play an increasingly important role. During this period, OFIs accounted for around a quarter of the growth in short-term deposits. In the first five months of 2006 OFIs contributed approximately 40% to the total growth in short-term deposits. This is noticeable since OFIs’ balances only account for around 5% of total short-term deposit holdings. Consequently, a high growth rate for short-term deposits held by OFIs can be observed from the beginning of 2005. The annual growth rate of short-term deposits held by OFIs rose from an average of 0.6% in 2004 to an average of 41.2% in 2005 and to an average of 67.4% during the first six months of 2006. This development was attributable to overnight deposits and deposits with an agreed maturity of up to two years. Repurchase agreements played only a negligible role.

\textsuperscript{21} Support by Ch. Probst is gratefully acknowledged.
\textsuperscript{22} Cf. Probst, Ch. (2006), Kursgewinne bei Aktienfonds, Rentenfonds leicht im Minus, Statistiken & Daten Analysen Q3/06.
IFs are the main OFI sub-sector. Consequently, the economic considerations that drive OFIs’ demand for money are mainly those that drive IFs’ demand for money (i.e. portfolio considerations). A trend towards asset accumulation through IFs by households can be observed. Hence, the scale at which IFs operate has increased. This development also has an impact on OFIs’ demand for money.

OFIs’ long-term deposits account only for a negligible fraction of total long-term deposits of the private sector. The annual growth rate of long-term deposits in Austria was around 2% during most of 2005. It dropped at the beginning of 2006 and even became negative in the second quarter of 2006. In Austria, the growth rate of long-term deposits was therefore relatively modest compared with that of other countries. The contribution of OFIs to the growth rate of long-term deposits was relatively high given their small share of outstanding amounts. However, other financial intermediaries were not the driving force behind the growth in long-term deposits. The decline in the growth rate of long-term deposits in 2006 was mainly attributable to households, but OFIs also contributed to the decline. On the other hand, ICPFs were the main sector with a positive impact on the growth rate of long-term deposits. Basel II and securitisation did not have any major impact on the behaviour of OFIs with regard to long-term deposits. Securitisation is – at least currently – not very widespread in Austria.

To sum up, OFIs’ deposit holdings to a large extent constitute short-term deposits. Taken together with the importance of IFs, this may suggest that OFIs’ deposit holdings primarily make up IFs’ short-term liquidity. IFs hold only a relatively minor share of their assets as deposits (4.6%), the larger part of their holdings being securities other than shares (54%), holdings of shares/other equity (16%), and holdings of IF shares (23.4%).

4.2.10 PORTUGAL

by D. Bonfim (Banco de Portugal)

The Portuguese OFI sector has grown considerably over the last few years. This part of the financial sector is composed mainly of IFs (excluding money market funds), FVCs, FHCs and FCLs.

As can be seen from Chart 34, IFs account for the largest part of OFIs’ total assets (31.4% in June 2006). Assets held by IFs grew over the last few years of the period under review. In fact, amid persistent negative real rates of return on time deposits, households (and other investors) channelled a significant share of their financial investments into life insurance and IFs. However, as regards IFs’ holdings of deposits and other similar investments, there was some decrease over the two and a half years up to June 2006, which may also have been caused by the relatively low returns on this type of investment.

Over the period under review, some new financial intermediaries recorded strong growth rates. Among these, securitisation funds and FCLs showed the more remarkable developments. Strong credit growth, accompanied by a moderate growth in deposits, led to an increased diversification of the banking system’s funding sources, among which loan securitisation played an important role. Against this background, assets held by resident securitisation funds recorded remarkable growth rates. Moreover, credit financial institutions are a new type of financial intermediary, which simultaneously carry out most lending activities, such as factoring, leasing or credit-purchase financing (the latter typically indirectly finance the purchase of specific goods and services by offering credit at retailers’ outlets). These institutions are included in the FCL sub-sector in Chart 34.

As far as monetary developments are concerned, the growth rate of the Portuguese contribution to euro area M3 increased at a lower pace than that of aggregate euro area M3 (3.9 percentage
points in Portugal between December 2003 and June 2006 compared with 7.5% in the euro area, using annualised growth rates). Short-term deposits (deposits and deposit-like instruments up to two years and deposits redeemable at notice) and repurchase agreements increased by 3.1 percentage points during this period, which was slightly below the 3.4% growth rate recorded at the euro area level (annualised growth rates). Short-term deposits held by non-financial corporations were one of the main contributors to this evolution. The contribution of other non-monetary financial intermediaries increased somewhat from early 2005 onward, although it remained at a fairly low level.

As regards the maturity structure of M3, the share of total short-term deposits in total deposits held by residents in Portugal decreased slightly during the period under review, from 97% to 90%. This notwithstanding, OFIs’ short-term deposit holdings recorded a strong increase between December 2003 and June 2006 (17.0% on an annual basis). It should be noted, however, that the share of OFIs’ short-term deposit holdings in total short-term deposits was only 5.0% in June 2006 (compared with 3.6% at the end of 2003) and therefore made a very modest contribution to M3.

To a large extent, the increase observed in Portuguese OFIs’ deposit holdings is likely to have stemmed from the buoyancy of their activity. IFs’ total deposits decreased over the period under review, meaning that the main contribution to the growth in OFIs’ short-term deposit holdings is most likely to have been caused by the growth observed in deposits held by OFIs other than IFs. Nevertheless, there is no information on the maturity structure of deposits held by each type of OFI, thus limiting the conclusions that can be drawn in this area. The available information suggests that the main contributions to the total growth rate of deposits held by OFIs are likely to be associated with deposits of FHCs.

Even though OFIs’ short-term deposit holdings accounted for only 5% of total short-term deposits in June 2006, its long-term deposit holdings represented 63% of total deposits with a maturity of over two years (compared with 5.6% in December 2003). Between the end of 2003 and June 2006, these long-term deposit holdings of OFIs recorded an extraordinary increase of 331.6% in annualised rates, implying a flow of new deposits of roughly €9 billion. Nevertheless, they did not affect the evolution of M3.

This remarkable increase reflects accounting changes resulting from the implementation of IAS/IFRS in early 2005. The new accounting framework introduced stricter criteria for the full removal of securitised assets from banks’ balance sheets. In the Money and Banking Statistics, securitised credit, which is not derecognised, continues to be recorded in banks’ loan book. However, the liquidity received by MFI’s from SPVs under the securitisation operation adds to banks’ cash holdings, hence generating a double record in banks’ assets. To offset this duplication, the counterpart of the liquidity received from SPVs under the securitisation operation is classified as deposits (and deposit-like instruments) of OFIs. However, it should be stressed that these deposits are merely a statistical
counterpart. In June 2006, 99% of OFIs’ long-term deposits referred to securitisation operations that were not derecognised.

Looking across the full maturity spectrum of OFIs’ deposit holdings, short and long-term deposits show very different evolutions. On one hand, OFIs’ deposits with maturities of up to two years (and thus included in monetary aggregates) recorded a strong pace of growth (although broadly in line with the asset growth of this sector) to account for 41% of OFIs’ total deposit holdings. In turn, OFIs’ deposits with maturities of over two years increased considerably from early 2005 onwards, as discussed above, which mostly reflected the statistical counterpart of liquidity obtained by banks with securitisation operations that were not derecognised from banks’ balance sheets. However, these long-term deposits did not affect the evolution of M3.

To sum up, the Portuguese OFI sector recorded a strong growth during the period under review, but its contribution to M3 growth was almost negligible. OFIs’ long-term deposit holdings increased very significantly, even though such an increase reflects only a statistical counterpart of the liquidity obtained by banks through securitisation operations.

4.2.11 SPAIN
by C. Martinez-Carrascal & M.-A. Menéndez (Banco de España)

In the last few years, the activity of the OFI sector has been concentrated in IFs, FVCs and SPVs issuing preference shares and other marketable securities.23 The increase in activity has been especially remarkable for FVCs, as well as for SPVs from the end of 2004. Consequently, their weight in the OFI sector significantly increased up to early 2006, with FVCs accounting for a third of OFIs’ assets in the first quarter of 2006 (see Chart 35). Although IFs remain the main sub-sector, accounting for nearly 50% of OFIs’ assets, their weight in this sector has decreased significantly, accounting for more than 85% of its assets at the end of the 1990s.

Short-term deposits and repurchase agreements included in M3 grew significantly in Spain in the last few years of the period under review (see Chart 36 and Chart 37). While at the beginning of 2004 their growth rate stood at 6.5%, it nearly doubled thereafter, reaching 12% year-on-year in mid-2006. Non-financial corporations and, more significantly, households made the largest contribution to this increase (their contribution to the growth rate of short-term deposits and repurchase agreements included in M3 increased by 1.7 and 3.4 percentage points respectively during this period to reach 3.5 and 5.9 percentage points respectively in mid-2006). The OFI sector’s contribution was not negligible either: during this period, it accounted for, on average, 1.4 percentage points of the increase in these deposits, the highest values being observed in early 2004 (around 3 percentage points). Subsequently, its contribution fell, and then increased again from mid-2005. As for other general government, its contribution was, on average, close to 1 percentage point during this period.

In Spain, FCLs are not considered to be OFIs but MFIs, which is why a zero value appears in the chart for the FCL position.

23 In Spain, FCLs are not considered to be OFIs but MFIs, which is why a zero value appears in the chart for the FCL position.
IFs account for a significant part of the short-term deposits held by the OFI sector. This sub-sector’s demand for money can be affected by the investment decisions of non-financial corporations and households, to the extent that these decisions involve allocation to IFs. Moreover, the IFs’ own portfolio allocation decisions, driven by the relative rates of return in the money, equity, bond markets or other assets, will affect their money-holding decisions. As for the other two main sub-sectors (FVCs and SPVs issuing preference shares and other marketable securities), they mainly hold – at least at the moment – MFI longer-term financial liabilities, not included in monetary aggregates. Consequently, their activity is not expected to significantly affect the evolution, and thus the indicator properties, of monetary aggregates.

In the last few years of the period under review, long-term deposits held by the OFI sector rose sharply in Spain (see Chart 38). Consequently, their weight in the long-term deposits held by the money-holding sector significantly increased,
more than doubling from the end of 2003 to nearly 70% in early 2006. In line with this increasing weight and the high growth rates of their long-term deposits, the OFI sector played a primary role in the developments of long-term deposits in Spain. From 2004 to mid-2006 the year-on-year growth rate of these deposits stood, on average, at 54%, the OFI sector accounting for nearly 80% of this increase.

Securitisation, together with the appearance of SPVs issuing preference shares and other marketable securities, accounted for a large part of the high growth rates of OFIs’ long-term deposit holdings towards the end of the period under review. As a result of legislative changes in order to implement IAS, from May 2005, the conditions for allowing securitised loans transferred to an FVC’s balance sheet to be removed from the credit institution’s balance sheet (and therefore to have no impact on OFIs’ deposits) are now more restrictive. The new regulation requires institutions to reinstate in their balance sheet any securitised loans granted since 2004 that had been derecognised without meeting the conditions set by the new regulations. This led to a significant increase in the OFI sector’s deposit holdings, resulting in this sector making a greater contribution to the growth rate of total long-term deposits held by the money-holding sector.

The maturity of deposits held by the OFI sector increased significantly in the last few years of the period under review. While in early 2003, long-term deposits accounted for somewhat less than 20% of total deposits, this percentage stood at around 70% in early 2006. This shift reflected the changes observed in the OFI sector’s activities, namely the larger weight in the OFI sector of FVCs and SPVs issuing preference shares and other marketable securities, which held a significant share of long-term deposits in their assets.

Regulatory changes significantly affected OFIs’ activities in Spain, specifically the activities of SPVs and securitisation through FVCs. A law on capital movements approved at the end of 2004 facilitated the development of SPVs issuing preference shares and other marketable securities activities. With the approval of this law, funds, which were previously raised by credit institutions via certain issues abroad by non-resident FVCs created by those credit institutions to benefit from fiscal advantages, are now often raised by the same procedure through resident FVCs. Furthermore, as a result of the legislative changes to implement IAS, securitisation had a more significant impact on OFI deposits from mid-2005 than previously.

4.2.12 FINLAND

by R. Herrala (Suomen Pankki – Finlands Bank)

Although growing quickly, the OFI sector is still relatively small in Finland. There are no comprehensive statistics about this sector available at present. However, the available information does suggest that the most important OFIs are IFs, which constitute around 80% of this sector by balance sheet share. IFs are typically established and run by banks and other financial institutions. During the past decade, the growth in IFs has been boosted.

Chart 39 OFIs’ holdings by sector

(percentages, March 2006)

- Security and derivative dealers: 0.6%
- Financial holding corporations: 19.0%
- Financial corporations engaged in lending: 1.7%

- Investment funds: 78.8%

Source: Suomen Pankki.
by increased marketing efforts by financial institutions and an increase in the demand for IF shares among the general public. FHCs constitute close to 20%, and other OFIs around 2%, of the OFI sector (see Chart 39).

In Finland, the annual growth in short-term deposits and other instruments included in M3 was between 4% and 8% between 2004 and mid-2006, while the market for repurchase agreements remained very small. In practice, the growth in deposits was accounted for by the growth in overnight deposits and deposits with an agreed maturity of up to two years. The Finnish OFI sector, in general, contributed positively to the growth rate of short-term deposits. After the household and the non-financial corporate sector, it was the third largest contributor to the growth in short-term deposits (see chart 40). At the end of the period under review, it held around 3% of all short-term deposits in Finland.

At present, not many analytical studies have been devoted to the topic of the determinants of the demand for money by the OFI sector in Finland. IFs are required by law to maintain “sufficient” cash balances. Some anecdotal evidence suggests that OFIs’ demand for short-term deposits is, in practice, largely driven by the transaction motive and, therefore, account balances are mainly used to settle securities transactions. Apart from the transaction demand, short-term account balances are held at a minimum level owing to opportunity cost considerations.

The growth of the OFI sector contributed positively to the growth in long-term deposits in Finland during the period from December 2003 to mid-2006. At the end of the period under review, the OFI sector held approximately 6% of all long-term deposits. OFIs’ demand for long-term deposits is driven mostly by other considerations besides securitisation and Basel II.

While the growth of the OFI sector contributed to both the growth in short-term and long-term deposits, the magnitude of its contribution to long-term deposits has clearly been more significant. Even during the period of low interest rates, OFIs tended to minimise their holdings of short-term deposits. There is, however, also some demand for long-term deposits by OFIs, mainly as a safe, long-term, interest-bearing financial investment.

4.2.13 DENMARK

by Ch. Petersen & K. Theill Jensen (Danmarks Nationalbank)

In Denmark, the OFI sector is clearly dominated by IFs (see Chart 41), which hold approximately 70% of the sector’s total assets. FHCs and FCLs also hold significant shares, with 20.9% and 8.8%, respectively. Notably, FVCs, which have generated increased deposit activity in euro area countries, are non-existent in Denmark.

The main issue regarding the OFI sector in the context of monetary aggregates (M2 and M3) is its holdings of and activity in short-term deposits and repurchase agreements. In the case of Denmark, it should be noted that M3 is
affected by technicalities concerning the issue of bonds to finance adjustable-rate mortgage loans. More precisely, short-term adjustable-rate loans, in principle, can be financed in two different ways. If the mortgage credit institutes have no open series with the desired coupon and maturity, the loans can be refinanced in new bond series with a short original maturity and the bond issues will be included in M3. If the mortgage credit institutes instead choose to finance the adjustable-rate loans in already open bond series with an original maturity of more than two years, those bonds will not be included in M3. Hence, the difference in the financing pattern is the main reason for the different development in the annual growth in M2 and M3 respectively. Therefore, in the Danish context, it seems more plausible to look at M2 rather than M3. Evidence shows that OFIs’ deposit holdings only account for about 5% of M2. While constituting only a minor share of total M2, OFIs’ short-term deposit holdings show a much higher volatility compared with the total money stock. As IFs are the only sub-sector for which Danmarks Nationalbank produces statistics, a complete picture of deposit holdings on a sub-sector level is not possible. It can be stated, however, that IFs’ share in the OFI sector’s total short-term deposit holdings is fairly stable at around 50%.

OFIs’ total short-term deposit holdings and repurchase agreements included in M3 have on aggregate risen from 2004 onwards. The annual growth rate of the OFI sector’s total short-term deposit holdings and repurchase agreements was quite high from the end of 2005 onwards, with annual growth rates in the region of 25% to 60%. This development could be explained by a slightly higher share of deposits compared with total assets, combined with an increase in the stock of assets in the OFI sector. Moreover, the annual growth rate of repurchase agreements was especially high during the period under review, but also quite volatile. Compared with other money-holding sectors, the Danish OFI sector has more or less a similar structure, where the main components of OFIs’ short-term deposits and repurchase agreements are overnight deposits (around 74% of the total) and deposits with a maturity of up to two years (around 21% of the total). Most of these deposits have a maturity of up to one year. Changes in the contributions to the annual growth
rate of short-term deposits and repurchase agreements were driven mainly by the development of overnight deposits and deposits with an agreed maturity of up to two years (see Chart 42). The strongest changes in growth rate contributions took place in 2006.

OFIs’ short-term deposit holdings and repurchase agreements stabilised around 5% when measured as part of M3 from the beginning of 2004 onwards. The annual growth rate of short-term deposits and repurchase agreements for the whole economy was around 10% in the period from 2004 to mid-2005, but a little higher during the rest of 2005 and the first half of 2006. The annual growth rate of the OFI sector’s short-term deposits and repurchase agreements increased from the end of 2005 onwards. In the same period, the growth rate of short-term deposits and repurchase agreements for households and non-financial corporations stabilised around 10% to 15% when measured on an annual basis. Households delivered the main contribution to the annual growth rate of total short-term deposits and repurchase agreements, but the contribution from the OFI sector increased slightly from the end of 2005 onwards (see Chart 43).

In general, the development in the OFI sector’s demand for money was driven largely by portfolio considerations, which depend on the relative rates of return in the money, equity and bond markets. The overall development in the annual growth rate of short-term deposits and repurchase agreements for all sectors and, more specifically, for the household sector should also be seen in the light of the strong growth of the Danish economy in 2005 and 2006.

From Chart 44 it can be concluded that the OFI sector does not play a significant role in the overall development of longer-term deposits in Denmark. This can be seen from the fact that the change in the OFI sector’s contribution to the overall growth in long-term deposits in Denmark remained somewhat constant around zero from the beginning of 2004 onwards. In addition, the OFI sector’s long-term deposit holdings relative to its short-term deposit holdings decreased over the last few years of the period under review to

less than 2%, while the average for all sectors was approximately 20%. This development in the OFI sector’s long-term deposit holdings has little to do with securitisation and Basel II, as there is and historically has been a very limited activity within true-sale securitisation in Denmark, which is also reflected in the non-existent population of FVCs and SPVs in the country.

Until 2006 the OFI sector did not influence the growth in M3 to a great extent. Quite notably, the peak in M3 in January 2006 was the direct effect of a temporary requirement for large deposits due to merger and acquisition activities. The deviation between M3 and M3 excluding the OFI sector in 2006 can also be related to these merger and acquisition activities, which created a significant amount of cash to be reinvested. A major part of these holdings were either directly or indirectly, through new placements from either households or pension funds, under the management of IFs, which created higher short-term deposit holdings among IFs, and thus in the OFI sector. Consequently, there is reason to believe that the above-depicted impact of OFIs on M3 should be seen as a temporary effect.

As a sub-sector, IFs grew in importance within the OFI sector from 2003 to 2005, at the expense of FHCs and FCLs. The explicit reason for this development was that IFs saw a significantly higher growth in their assets during this period than the other two sub-sectors, which experienced declining growth rates. This can be attributed mainly to a new regulation in 2004, which allowed for the establishment of limited-membership associations, i.e. IFs are allowed to receive funds from only a few large investors, such as pension funds, and not from the general public. This resulted in several large pension funds, such as Lønmodtugernes Dyrtdsfond24, Særlege Pensionsordning25 and Arbejdsmarkedets Tillægs Pension26 establishing this type of investment association.

Overall, the OFI sector has grown by around 65% measured in assets from 2003 to 2005, which, of course, is significant above the growth in the Danish economy. As shown above, this can be attributed mainly to the development inside the IF sub-sector. Besides the above-mentioned regulation regarding limited-membership associations relating to the OFI sector, a legal framework for the regulation of hedge associations (hedge funds) was introduced in 2005. The size of the Danish hedge funds’ assets is quite small compared with the value of the total assets in the Danish capital markets. Moreover, it is still difficult to draw any conclusions on hedge fund activity owing to the relatively short period of time such funds have existed in Denmark.

4.2.14 SWEDEN

by M. Karlsson (Sveriges Riksbank)

As can be seen from Chart 45 the main OFI sub-sector in Sweden is IFs, followed by investment corporations and “non-monetary securities companies and investment firms”. The residual category of other OFIs includes, for example, non-monetary credit market corporations and financial intermediaries.27

24 Frozen cost-of-living allowances fund.
25 Special Pension Scheme.
26 The Labour Market Supplementary Pension Scheme.
27 The figures refer to the financial accounts tables. The division of sub-sectors might slightly differ from the one commonly used within the Eurosystem.

49
Over the last three or four years of the period under review, the OFI sector experienced quite a stable development in MFI short-term deposits. This notwithstanding, the respective time series shows a significant jump in December 2004 and, after that, a stabilisation at a higher level (see Chart 46).28

Looking over the last five years on the basis of financial accounts data, the OFI sector recorded a very stable development in short-term deposits which remained on the same level from December 2001 onwards. 29 The allocation of the deposits is between transactions accounts and deposits with an agreed maturity of up to three months. Repurchase agreements were much more volatile. An analysis of the last three years of the period under review shows that IFs (above 95% of all repurchase agreements in the OFI sector) peaked at the end of 2005 and at the beginning of 2006 and thereafter declined towards a more stable longer-term value.

According to the MFI Balance Sheet Item statistics, the OFIs’ deposit holdings increased somewhat. Financial account data show the same level, but with a less pronounced volatility. Repurchase agreements were quite volatile, which also, to some extent, holds true for deposits with a maturity of more than three months. Compared with the OFI sector, households depict a much smoother increase, while non-financial corporations report a steeper increase. The repurchase agreements of non-financial corporations were also quite volatile. Households and non-financial corporations also held longer-term deposits, while the OFI sector did not seem to invest in these assets at all (see Chart 47). The Swedish OFI sector did not appear to have any influence on longer-term deposits as the amounts involved were rather small and, from an economic point of view, negligible. Overall, OFIs in Sweden only hold deposits that are included in M3.

28 The figures are derived from Balance Sheet Item Statistics.
29 This result is based on the figures from the financial accounts.
4.2.15 UNITED KINGDOM

by J. Thomas (Bank of England)

In the United Kingdom, the OFI sector is known as the Other Financial Corporations, or OFCs sector, whose main sub-sectors are:

(i) non-bank credit grantors excluding credit unions – include non-deposit taking financiers and other specialist lenders, such as credit card companies;

(ii) mortgage and housing credit corporations – specialist companies providing mortgage finance;

(iii) investment and unit trusts (excluding money market mutual funds) – unit trusts, property trusts and open ended-investment companies;

(iv) bank holding companies – holding institutions that are not part of the banking sector;

(v) securities dealers – gilt-edged market makers, inter-dealer brokers, etc;

(vi) other financial intermediaries – other specialist finance agencies who grant credit including venture capital companies outside of the UK banking sector and specialist underwriters of share issues and other securities;

(vii) activities auxiliary to financial intermediation – credit and finance brokers, bureaux de change, damage evaluators and loss adjusters (see Chart 48)

Unfortunately, in the United Kingdom, no data on the individual short-term deposits and repurchase agreements of OFIs or the individual industrial sectors are collected. However, from 2003 onwards it is possible to estimate the percentage contribution of OFCs’ repurchase activities to both aggregate and OFCs’ M4. These data show that the respective contributions increased during the period under review. It can be assumed that a similar pattern holds true for the OFI sector overall.

Analytical work carried out within the Bank of England suggests that OFIs’ real money demand depends positively on, first, their real wealth (measured by their total financial assets), second, the spread between the own rate on corporate deposits and the three-month Treasury/commercial bill rate (“money market” spread), third, the spread between the own rate and the three-month return on equities (“equity market” spread) and, finally, the real deposit rate. Among the variables mentioned above, the key drivers are wealth and the money market spread.

Conceptually, some of these factors also help to drive the money-holding behaviour of households and non-financial corporations. For example, non-financial corporations’ money demand depends on their wealth and a money market spread. However, it also depends on investment and the real cost of capital. Similarly, household money demand depends on wealth and a money market spread, as well
as on the households’ real disposable income and inflation.

Under current UK (Basel I) regulations, banks can achieve regulatory capital relief by securitising assets. As banks are required to hold relatively large amounts of capital against residential mortgage exposures under Basel I, this has been one of the factors driving issuance of residential mortgage-backed securities (RMBS). Covered bond issuance has only recently become more widespread in the United Kingdom. The introduction of Basel II may lead to a reduction in the issuance of residential mortgage-backed securities in favour of covered bonds.

OFIs’ share of broad money holdings rose from around 2% in 1965 to around 25% at the end of the period under review. This increase was accompanied by a decline in households’ share of holdings from around 80% to around 60%. These developments partly reflect a relative shift in household savings away from direct holdings of bank deposits towards financial intermediaries, such as retail unit trusts, as well as the build-up of households’ wealth held in the form of pension savings. Over the same period, the rate of growth of OFIs’ broad money holdings was far more volatile than that of non-financial corporations or households.

4.3 AN OVERALL VIEW

Taking an overarching perspective, the documented evidence confirms the considerable heterogeneity in the structure and importance of OFIs across countries. Some commonalities, however, can be detected. First, in most euro area countries, the largest OFI sub-sector is IFs, which seem to hold short-term deposits with MFIs in order to manage their liquidity risk, as most IFs are legally required to maintain the liquidity of their unit shares. From an economic perspective, OFIs’ demand for money is determined by portfolio allocation decisions based on the relative rates of return in the money, equity, bond markets or other assets. Moreover, OFIs transactions demand for money is likely to be closely related to the need to settle financial transactions. Second, in several countries, repurchase agreements account for a much larger share of M3 deposit holdings than observed for other money-holding sectors, as they are used as the usual means of securing the borrowing/lending of cash and securities. Third, in a number of Member States, securitisation through SPVs may have contributed to the demand for MFI deposits. However, country-specific factors and the type of securitisation undertaken (“true-sale” or “synthetic”) has played a role in the maturity of the deposits, and thus in whether or not they impacted on M3 or longer-term financial liabilities.
5 CONCLUSIONS
by Ph. Moutot (ECB staff)

A number of conclusions can be drawn from this extensive analysis. Both on theoretical and empirical grounds, the monetary nature of inflation is not brought into question by the strong growth in OFIs’ deposit holdings. However, given the predominant portfolio considerations in their demand for liquid assets, the impact of OFIs on monetary dynamics raises a particular set of challenges when assessing the medium to longer-term risks to price stability from monetary developments.

One aspect of addressing these challenges is the need for a more detailed sectoral analysis of money and credit, including of the OFI sector. More specifically, three key issues deserve closer attention in the future, as follows.

- Eliminating some of the existing statistical shortcomings, such as the lack of timely and frequent data with a good level of detail and coverage, as well as long time-series data on the various OFI sub-sectors. In this respect, the planned improvements to IF data, transactions data and data on financial corporations currently being discussed within the ESCB’s Statistics Committee (for instance, regarding a more detailed breakdown) are very promising.

- The need to identify, by means of appropriate techniques, the impact of OFIs on monetary developments, the indicator properties of money and the monetary policy transmission mechanism. Among other things, the direct modelling of OFIs’ money demand, the impact of including or not including OFIs in M3, as well as assessments of the impact of OFIs’ deposit holdings on indicator model results (Bayesian, Stock and Watson techniques, etc.) are seen as a useful way to proceed.

- The rising importance of OFIs in the financial sector in recent years, which will have implications not only for monetary developments, but also for the functioning of the financial system as a whole.

Against this background, it can be suggested that further work to foster the understanding of OFIs’ demand for deposits and its implications for price stability will remain an important aspect of monetary analysis in the coming months and years. However, ultimately, a better understanding of the motives of OFIs’ money demand and credit demand rests on a deeper investigation into the economic rationale for the existence of these entities. Such an analysis was however beyond the scope of this paper and is left for future research.
ANNEX
by A. Matas Mir (ECB staff)

This annex presents a short quantitative analysis of the financial relationships between the MFI and the different OFI sub-sectors, based on a dataset including all euro area countries except Ireland and Slovenia. Balance sheet data on the OFI sub-sectors IFs, FCLs and SDDs comprising loans and deposits are compared against MFI balance sheet data on loans and deposits with OFIs. The objective of the analysis is to determine which particular OFI sub-sectors (if any) is, in each country, dominating the MFI credit/deposit transactions with the domestic OFI sector considered as a whole. Although the limitations of the data currently available (such as absence of counterparty, counterpart area and maturity breakdowns in the OFI data and absence of a breakdown by type of OFI in the MFI data) prevent a more comprehensive exercise, some of the results obtained are still worth discussing.

The deposit liabilities of MFIs with the OFI sector seem to be, in general, dominated by the

Results in each line are based on the cointegrating regression between series (a), which is based on MFI’s statistical returns and refers to business with total domestic OFIs (plus financial auxiliaries) and series (b), which is based on the available short-term approach OFI data and refers to deposits/loans of an individual OFI sub-sector. Notice, that series (b) are only available as a total with no maturity counterparty or instrument breakdown. Series are prefiltered for large breaks and/or additive outliers using TRAMO/SEATS, with detected outliers indicated in column.

(f) Only results for which the null of no cointegration could be rejected at the 10% level using an ADF test are presented.

(1) Series (a) used in cointegrating regression is MFI loans to OFIs < 5 years minus loans taken by SDDs.

(2) Short-term deposits = all deposits except those with agreed maturity over 2 years and those to notice of redemption over 3 months.

---

For more details on the methodology used, please refer to the notes accompanying Table 3. The analysis is restricted to MFI domestic positions (hence cross-border positions with OFIs are excluded) because of the impossibility of isolating the residency of the counterparty in the currently available data on “loans and deposits taken” in the balance sheet of OFIs.

ECB
Occasional Paper No 75
October 2007
54
activities of IFs according to results presented in Table 3.1. Indeed, developments in various types of MFI short-term deposit, as indicated in column (a) of the table, are significantly explained by developments in the IF series “Deposits placed” in Germany, Spain, France, Luxembourg and Portugal, with the other OFI categories having only a residual importance.

The liquidity buffering needs of open-ended investment funds, as well as liquid positions held by all fund types for speculative purposes, possibly explain the prominent role of IFs in the placement of deposits by the OFI sector as a whole.

In turn, MFI credit to the OFI sector does not appear to be driven by IFs, according to the available data (see Table 3.2). Only in two countries, Germany and Luxembourg, does the series “IF deposits and loans taken” explain a significant proportion of total MFI lending to the OFI sector in any given maturity band, with the case of Germany being irrelevant in terms of impact on overall private sector lending (see column (g)). Notwithstanding the limitations of the present analysis, it would thus appear that high leverage is not a main feature of the IF sector as a whole.

Lending to FCLs appears to play an important role in Portugal, which has experienced recently an important expansion in factoring, leasing and credit-purchase transactions carried out by non-MFIs (see section IV.2.10) and even more so in Italy, where a significant proportion of lending to the private sector appears to be channelled through these specialised lenders. Indeed, Italian FVCs account for around 30% of the financial assets of the domestic OFI sector (see section IV.2.6), whilst the order of magnitude of their liabilities in the form of loans is roughly equivalent to 10% of all MFI domestic loans to the private sector.

Finally, lending to SDDs seems to be the most important component of short-term lending to the OFI sector in France, with a quantitatively significant impact in total MFI lending. Although an instrument breakdown is currently not available, it is likely that most of these positions correspond to reverse repurchase agreements, reflecting collateralised cash borrowing from MFIs by the securities firms and/or their securities lending to MFIs against cash collateral.

31 This is suggested by the fact that the addition of SDDs and/or FCLs data (when available) as additional conditioning variables in regressions of the form presented in Table 3.1 and their dynamic extensions did not significantly change their overall results after correcting for spurious goodness-of-fit increases. Note also that the absence of data for the FVC sub-sector could explain the fact that similar relationships were not found to be significant in other countries (although this caveat would apply mainly to longer-term deposits).

32 The deposit categories involved would also be consistent with IFs holding positions as margin deposits in the context of hedging strategies and/or speculative positions in derivatives, or as cash collateral when borrowing securities from MFIs. However, given the level of limited breakdown detail in the OFI data currently available, it is not possible to quantify the overall importance of those positions.

33 In Luxembourg, short-term “deposits and loans taken” by IFs could potentially explain a relevant part of total domestic MFI credit. However, this would be more a reflection of the large size of the IF industry relative to the rest of the domestic private sector in Luxembourg. In addition, the available IF data does not allow to discern whether those “deposits and loans taken” reflect the activity of investment funds pursuing non-traditional investment strategies (e.g. highly geared funds), versus that of traditional funds engaged in repurchase agreements with MFIs (e.g. securities lending to MFIs by long-only, non-leveraged funds).
