Center Discussion Paper No. 188

THE RATE OF SURPLUS VALUE IN PUERTO RICO

by

Edward Wolff

October 1973

Note: Center Discussion Papers are preliminary materials circulated to stimulate discussion and critical comment. References in publications to Discussion Papers should be cleared with the author(s) to protect the tentative character of these papers.

## THE RATE OF SURPLUS VALUE IN PUERTO RICO

In Economic Philosophy, Joan Robinson makes the following remarks about Marx's theory of value:

. . . The whole argument (of value) appears to be metaphysical. It provides a typical example of the way metaphysical ideas operate. Logically it is a mere rigmarole of words but for Marx it was a flood of illumination and for latter-day Marxists a source of inspiration.<sup>1</sup>

Leontief is more positive on the accomplishments of Marx: "Marx was the great character reader of the Capitalist system."<sup>2</sup> But, he adds: "As many individuals of this type, Marx had also his rational theories, but these theories in general do not hold water."<sup>3</sup>

This paper sets out to give an algebraically consistent and empirically operational estimation of the rate of surplus value.<sup>4</sup> The rate of surplus value is computed for years 1948 and 1963 in Puerto Rico, and the change in the rate of surplus value is decomposed into three effects: the first from technological change, the second from a rising real wage and the third from a change in the pattern of consumption. Additional

<sup>3</sup> Ibid, p.98.

<sup>4</sup> To the author's knowledge, this is the first such attempt of the kind. For example, Baran and Sweezy in Monopoly Capital use a concept of surplus which does not involve the transformation of market prices into labor values. Moreover, Arghiri Emmanuel in Unequal Exchange assumes throughout his analysis that total profits equal total surplus value.

observations on the transformation from market prices to labor values, the organic composition of capital and the treatment of imports are also included.

Puerto Rico is chosen for this study because of the tremendous transformations the economy undergoes during these years.<sup>5</sup> Between 1948 and 1963, real per capita income more than doubles, as does labor productivity. Investment increases as a share of GNP from 12.5% to 20%. Agriculture (including food processing) falls as a share of value added from 29% to 18%, and manufacturing rises from 15% to 22%. Puerto Rico becomes transformed from a plantation economy to a modern industrial economy. The magnitude and scope of the changes in the Puerto Rican economy thus provide a significant test of the effect of technological change on the rate of surplus value.

---

<sup>5</sup> An additional consideration was the availability of input/output data for both 1948 and 1963.

# I. THE MODEL

In order to compute the rate of surplus value, input/output flows in market prices ("prices" for short) must be converted into input/output flows in labor values ("values" for short). Two steps are needed. The first step is to transform the input/output flow table in price terms into an accounting framework conformable with Marxian theory.

The original input/output tables<sup>6</sup> are arranged as follows:

- (i) A: 26 by 26 matrix of total inter-industry flows.
- (ii) U: 8 by 26 matrix of value added by sector, showing wages, profits, rent, interest, transfers, taxes, depreciation, and other value added.
- (iii) F: 26 by 6 flow matrix showing household consumption, capital formation (plant and equipment investments), net inventory change, government expenditures, exports, and imports (as a negative flow).

Thus:

$$(1) \sum_{j=1}^{26} A_{ij} + \sum_{j=1}^6 F_{ij} = X_i \quad (2) \sum_{i=1}^{26} A_{ij} + \sum_{i=1}^8 U_{ij} = X_j$$

The value added matrix U is aggregated into three rows: W, wages; S, surplus, including profits, rents, interest, transfers, taxes, and other value added; and D, depreciation. In Marxian theory, depreciation is considered endogenous, since constant capital includes both produced inputs (intersectoral flows) and the depreciation of fixed capital. D thus becomes an endogenous row. In order to create a column corresponding

---

<sup>6</sup> The 1948 Puerto Rican input/output table was prepared by Amor Gosfield and was obtained from the Harvard Economic Research Project. The 1963 table was obtained on tape from La Junta de Planificación, Santurce, Puerto Rico. The tables were reconciled and aggregated to their 26 order level by Richard Weisskoff.

to D, the gross capital formation column is split proportionately into N, depreciation, and net capital formation<sup>7</sup> such that  $\Sigma N = \Sigma D$ . Let:

(iv)  $B = \begin{bmatrix} A & N \\ D \end{bmatrix}$ , the adjusted 27-order inter-industry flow matrix.

The household consumption column in F, moreover, is split proportionately into workers' consumption, C, and capitalists' consumption,<sup>8</sup> such that  $\Sigma C = \Sigma W$ . To capitalist consumption are added net capital formation, net inventory change, government, and exports less imports to form K, the surplus consumption column. Thus:

$$(3) \sum_{j=1}^{27} B_{ij} + C_i + K_i = Z_i$$

$$(4) \sum_{i=1}^{27} B_{ij} + W_j + S_j = Z_j$$

With the input/output flow matrices in price terms arranged in a form consistent with Marxian theory, the second step is to transform the flows from prices to values. A transformation scheme worked out by Morishima and Seton<sup>9</sup> is employed.

Define the 27 order matrix of row coefficients Q such that:

$$(v) Q_{ij} = \frac{B_{ij}^p}{Z_i^p} = \frac{B_{ij}^v}{Z_i^v}$$

where the superscripts "p" and "v" refer to prices and values, respectively. Define the 27-order matrix R, such that:

<sup>7</sup> In principle, a capital coefficient matrix should be used to determine the actual composition of the depreciation column. Such matrices are unavailable for Puerto Rico.

<sup>8</sup> Three assumptions are implicit in this: (1) Workers do not save. (2) The pattern of consumption is the same for worker and capitalist. (A preferable procedure, if data were available, is to estimate the consumption mix of worker and capitalist separately). (3) The value of labor power is equivalent to the average consumption of labor.

<sup>9</sup> M. Morishima and F. Seton, "Aggregation in Leontief Matrices and the Labour Theory of Value," *Econometrica* Vol. 29 No. 2 April 1961

$$(vi) R_{ij} = \frac{C_i^P}{Z_i^P} \cdot \frac{W_j^P}{\Sigma W^P} = \frac{C_i^V}{Z_i^V} \cdot \frac{W_j^V}{\Sigma W^V}$$

Thus,  $R_{ij}$  shows the proportion of output of each sector "i" consumed out of wages by workers of sector "j". Define  $r$  such that:

$$(vii) W^V + s^V = r W^V$$

Hence, the rate of surplus value<sup>10</sup> is equal to  $r-1$ . As a result,

$$(5) [1/r I - (I - Q')^{-1} R'] Z^V = 0 \quad \text{and}$$

$$(6) \Sigma Z^P = \Sigma Z^V$$

give the rate of surplus value and the vector of labor values.

---

<sup>10</sup> It is implicitly assumed that the rate of surplus value is the same in each sector.

## II. Preliminary Observations

## II. PRELIMINARY OBSERVATIONS

Columns 1 and 2 of Table 1 show the ratio of profits (surplus in price terms) to wages (also in price terms) and the ratio of values to prices by sector for 1948.<sup>11</sup> (Row 28 shows the weighted average of profits to wages and of values to prices). It is evident that the ratio of values to prices tends to be low when the ratio of profits to wages is high, and vice versa. Agriculture (1), chemicals (10), and real estate (24) have the highest profit to wage ratios and the lowest value to price ratios; sugar cane (2), paper products (8), printing (9), communications (20), and government services (26) show, with the exception of other manufacturing (15) and trade (21), the lowest ratios of profits to wages and the highest ratios of value to price. The correlation coefficient, as a measure of association, between the two sets of ratios (with the weighted means used instead of the unweighted) is  $-.5102$ .

Columns 1 and 2 of Table 2 give the same sets of ratios for 1963. The four sectors with the highest ratios of profits to wages--agriculture (1), processed foods (4), chemicals (10), and real estate (24)--yield the lowest ratios of value to price; sugar cane (2), textiles (5), leather (6), paper (8), printing (9), construction (16) and government services (26), on the other hand, show the lowest ratios of profits to wages, with the exception of furniture (7) and mining (14), and the highest ratios of value to price. The correlation coefficient (using the weighted means) between the two vectors of ratios is  $-.7559$ .

---

<sup>11</sup> All computations are performed using I.O.P.E. (See Wolff, Edward, "I.O.P.E.: Input/Output Program for Economists," *Annals of Economic and Social Measurement*, July, 1973).

The strong inverse relation between the profit-wage ratio and the value-price ratio can be explained as follows: The ~~eigen~~ value transformation here employed is mathematically equivalent to an iterative algorithm which first distributes the surplus proportionately to the wages in each sector, then distributes the resulting gross outputs across the rows of B, C, and K, and lastly, adjusts the wage flows in each sector such that total wages is equal to total (adjusted) worker consumption. Thus, in the first step, the gross output of those sectors with a ratio of profits to wages exceeding the overall average is lowered, and the gross output of those sectors with a ratio below the average is raised. In the second step, the gross output of those sectors using inputs whose gross output is raised in the first step (that is, with an initially low ratio of profits to wages) is raised, and vice versa. In net, it appears that the final ratio of value to price depends primarily on the initial ratio of profits to wages--that is, on the first step of the first iteration.<sup>12</sup>

(b) In Table 3 below are shown the rate of surplus value and the ratio of profits to wages (in price terms) for 1948 and 1963.

TABLE 3  
The Rate of Surplus Value and  
the Profit to Wage Ratio

	<u>Rate of Surplus Value</u>	<u>Profits/Wages (in prices)</u>
1948:	.9729	.5907
1963:	.9328	.7529

---

<sup>12</sup> This iteration was also performed. Convergence occurred in 15 iterations for the 1948 table and 11 for the 1963 table.

There are two striking results. The first is that the rate of surplus value is almost constant in the two years, falling by 4.1 per cent. The second is the high level of surplus value,<sup>13</sup> around .95. The ratio of profits to wages, on the other hand, changes considerably, rising by 27.5 per cent, and is substantially lower than the rate of surplus value. The ratio of profits to wages is thus a poor proxy for the rate of surplus value, in terms of absolute amount, magnitude of change, and even direction of change.

The reason that the rate of surplus value is higher than the profit to wage ratio in the two years becomes apparent in examining Column 3 of Tables 1 and 2, the composition of worker consumption (in current prices). Workers tend to consume those products whose labor value is less than its price. In 1948 the chief consumption items are agriculture (1), processed foods (4), textiles (5), metals (13), hotels and restaurants (17), real estate (24), transport (25), and government services (26). Only three of these sectors have a ratio of value to price greater than 1. In 1963, the principal consumption items are agriculture (1), processed foods (4), textiles (5), metals (13), personal services (23), real estate (24), transport (25), and government services (26). Here, too, only three of these sectors have a value to price ratio greater than 1. The correlation coefficient between the ratios of value to price and the sectoral consumption shares is  $-.5102$  in 1948 and  $-.4612$  in 1963.<sup>14</sup> Thus, though workers consume a relatively

---

<sup>13</sup> It is interesting to note that Marx uses a rate of surplus value of 100% in most of the numerical examples in Capital.

<sup>14</sup> In 1948, we omit leather (6), petroleum and coal (12), and mining (14) which consist exclusively of non-competitive imports. In both years we use the weighted mean of value to price.

high proportion of gross domestic product in real terms, the proportion is relatively less in terms of embodied labor. As a result, the cost of reproducing the worker is less in labor value terms than in market price terms. Hence, the rate of surplus value is greater than the ratio of profits to wages.

(c) Table 4 shows the organic composition of capital<sup>15</sup> in value and price terms for 1948 and 1963.

TABLE 4  
The Organic Composition of Capital

	Constant/Variable Capital (Value terms)	Constant/Variable Capital (Price terms)
1948:	2.7479	2.4423
1963:	2.0866	1.9706
Change:	-24.1%	-19.3%

The striking result is that the organic composition falls considerably during the two periods, in both price and value terms. Marx argues that the organic composition tends to rise over time since new technology, on average, embodies a higher constant capital to labor ratio in physical terms (that is, a higher technical composition). Marx does acknowledge, however, the presence of an offsetting tendency--namely, that as technology advances, the value of inputs tends to fall, since the labor embodied in these inputs

---

<sup>15</sup> Here we use the ratio of constant to variable capital for the organic composition. The preferable concept is the ratio of the stock of capital plus the value of produced inputs consumed during and the depreciation occurring in one turnover period to the wages advanced in one turnover period. (See Marx, Karl, Capital, Volume 3, International Publishers, New York, 1967, p. 158.) Since capital coefficients and turnover data are unavailable, the ratio of the value of produced inputs and depreciation per annum to the wages paid out per annum is used instead.

declines.<sup>16</sup> Even though, in other words, the technical composition rises, the labor value of the new means of production tends to decline. The decline in the organic composition seems due to the latter effect outweighing the former.

(d) Table 5 shows the surplus in price and value terms for 1948 and 1963.

TABLE 5  
The Surplus in Price and Value Terms  
(in 1000's)

	<u>Surplus (Value)</u>	<u>Surplus (Price)</u>
1948:	284130	206013
1963:	1125461	980558

Marx argues that total surplus value equals total profits, given that total values equal total prices.<sup>17</sup> Many economists have pointed out the inconsistency of these two propositions.<sup>18</sup> Here total surplus value exceeds total profits for both 1948 and 1963.

---

<sup>16</sup> Marx, Karl, Capital, Volume 3, Op. cit., p. 236.

<sup>17</sup> Ibid, p. 138.

<sup>18</sup> Cf. Sweezy, Paul, The Theory of Capitalist Development, Modern Reader Paperbacks, New York, 1968, Chapter 7.

### III. EXPORTS AND IMPORTS

The presence of imports creates a special problem in the transformation of prices to values. Since inputs are not produced domestically, they cannot be valued according to the amount of (domestic) labor embodied in them. Imports can, however, be valued according to the labor costs involved in obtaining them--namely, the labor embodied in exports. In order to take this into account analytically, the inter-industry flow matrix can be augmented with an endogenous import row and export column. Let:

$$(viii) \quad B = B_d + B_m$$

$$(ix) \quad C = C_d + C_m$$

$$(x) \quad D = K_d + K_m$$

where subscripts "d" and "m" indicate domestically produced and imported goods, respectively. Let "E" be the vector of exports, and

$$(xi) \quad L_d = K_d - E^{19}$$

$$(xii) \quad L_m = K_m$$

Define:

$$(xiii) \quad \bar{B}_m = \sum_{i=1}^{27} (B_m)_{ij}$$

$$(xiv) \quad \bar{C}_m = \sum C_m$$

$$(xv) \quad \bar{L}_m = \sum L_m$$

---

<sup>19</sup> Note that there are no direct imports into exports.

Also,

$$(xvi) \quad \tilde{B} = \begin{bmatrix} B_d & E \\ \tilde{B}_m \end{bmatrix}, \quad \text{a 28-order matrix}$$

$$(xvii) \quad \tilde{C} = \begin{bmatrix} C_d \\ \tilde{C}_m \end{bmatrix}, \quad \text{a 28 by 1 vector}$$

$$(xviii) \quad \tilde{L} = \begin{bmatrix} L_d \\ \tilde{L}_m \end{bmatrix}, \quad \text{a 28 by 1 vector}$$

$$(xix) \quad \tilde{W} = (W \ 0), \quad \text{a 1 by 28 vector}$$

$$(xx) \quad \tilde{S} = (S \ 0), \quad \text{a 1 by 28 vector}$$

Thus,

$$(7) \quad \sum_{j=1}^{28} \tilde{B}_{ij} + \tilde{C}_i + \tilde{L}_i = \tilde{Z}_i \quad i=1, 28$$

$$(8) \quad \sum_{i=1}^{28} \tilde{B}_{ij} + \tilde{W}_j + \tilde{S}_j = \tilde{Z}_j \quad j=1, 27$$

As indicated by Equation 8, it is not necessary that total imports equal total exports in price terms in order to transform prices into values. However, when the transformation is performed, the total labor value of imports is forced equal to the total labor value of exports, since the value of imports is implicitly defined in this way. We therefore set:

$$(xxi) \quad Q_{ij} = \frac{\tilde{B}_{ij}}{\tilde{Z}_i}$$

$$(xxii) \quad R_{ij} = \frac{\tilde{C}_i}{\tilde{Z}_i} \cdot \frac{\tilde{W}_j}{\sum \tilde{W}_j}$$

The Rate of Surplus Value in Puerto Rico  
 III. Exports and Imports

Thus,

$$(9) \quad [1/r \ I - (I - \tilde{Q})^{-1} \tilde{R}'] \tilde{Z}^v = 0$$

$$(10) \quad \sum_{i=1}^{27} \tilde{Z}_i^p = \sum_{i=1}^{27} \tilde{Z}_i^v \quad (20)$$

The rate of surplus value in 1948 jumps to 131.35% and the rate of surplus value in 1963 to 118.47%. The reason for this is as follows: In 1948 there is a very large balance of trade deficit, with a ratio of imports less exports to imports of .37. When transformed to labor values, imports become significantly depreciated in relation to domestically produced goods. In fact, the ratio of imports in labor value terms to imports in prices is only .68. Workers, moreover, consume a higher percentage of imports than the recipients of the surplus:  $\bar{C}_m / \Sigma C = .41$ , whereas  $\bar{L}_m / \Sigma L = .20$ . The labor value of wage goods is thus significantly reduced, and the rate of surplus value, as a result, increases. Marx, in fact, argues that foreign trade cheapens the necessities of life and thereby raises the rate of surplus value.<sup>21</sup> In 1963 the trade deficit is smaller, with a ratio of imports less exports to imports of .16. The ratio of imports in value terms to imports in price terms is .84;  $\bar{C}_m / \Sigma C = .39$ ; and  $\bar{L}_m / \Sigma L = .15$ . Thus, the rate of surplus value also rises in 1963, but not as much as in 1948.

The results presented in this section do not, it is felt, accurately reflect the rate of exploitation in Puerto Rico, because of the extreme

<sup>20</sup> Note that imports (and therefore exports) are excluded in equating total values to total prices.

<sup>21</sup> Marx, Karl, op. cit., p. 237.

The Rate of Surplus Value in Puerto Rico  
III. Exports and Imports

sensitivity of the rate of surplus value to the balance of trade deficit, the ambiguous meaning of the balance of trade for Puerto Rico,<sup>22</sup> and the unreliability of the trade data for the island (especially imports in 1948). In Section IV, the model presented in Section I is again employed.<sup>23</sup> It is felt, nonetheless, that this section fills an important gap in Marxian value theory.

---

<sup>22</sup> Puerto Rico's currency is American dollars, and its major trading partner is the United States.

<sup>23</sup> Two clarifications of the model are in order. First, competitive imports are valued according to the labor value of domestic substitutes. Second, non-competitive imports can be valued only in terms of exports, since there is no domestic production of them. Therefore, an endogenous non-competitive import row is added, and exports are divided proportionately into an endogenous and exogenous component such that the sum of non-competitive imports equals the sum of endogenous exports.

## The Rate of Surplus Value in Puerto Rico

## IV. Relative Surplus Value

## IV. RELATIVE SURPLUS VALUE

Consumption per worker rises from \$867 in 1948 to \$2,107 in 1963.<sup>24</sup> Though the real wage increases by 143%, the man years, in labor value terms, embodied in the per worker consumption basket (the ratio of variable capital to variable capital plus surplus value) rises from .5069 to only .5174--that is, by 2.6%. In both 1948 and 1963, in other words, the annual consumption per worker (his cost of reproduction) is the equivalent of approximately one-half a man year of labor. This, moreover, is equivalent to a constant rate of surplus of approximately 100%. The uniformity of the rate of surplus value in the face of the tremendous increase in the real wage is accounted for by an increase in relative surplus value. This, in turn, is due to two factors: (1) the fall in the labor value of the means of production used in producing wage goods; (2) the fall in the labor value of the means of subsistence, partly a consequence of factor 1.

Column 1 of Table 6 shows the labor value of the product of each sector in 1948, Column 2, the labor value of the product of each sector in 1963, and Column 3, the ratio of the two.<sup>25</sup> We can see that the value of output of every sector declines.<sup>26</sup> The ratios range from a high of

---

<sup>24</sup> All price flows in this section, unless otherwise noted, are in constant 1963 prices. Price indices were computed by sector and supplied by Richard Weisskoff.

<sup>25</sup> Labor value is defined here as the number of man years embodied in the output of a sector per \$1,000 of sectoral output. The preferable concept is the labor embodied in one (physical) unit of output. Constant prices are used as a proxy for physical units, since disaggregated commodity flow matrices are unavailable. (See Morishima and Seton, op. cit., for an analysis of the error resulting from aggregation.)

<sup>26</sup> Sectors 6, 12 and 14 do not exist in 1948 and are excluded from the comparison.

The Rate of Surplus Value in Puerto Rico  
IV. Relative Surplus Value

.5325 (indicating a relatively small decline) in real estate (24) to a low of .2871 in sugar cane (2). Other large falls occur in paper products (8), water and sanitation (19), and communications (20). The fall in the ratio of total output in thousands of 1963 dollars to total embodied labor in man years is from .7110 to .2650 (row 28).

The movement of the rate of surplus value over time can be decomposed into three components: the effect of technological change, the effect of a change in total per worker consumption, and the effect of a change in the pattern of consumption. These effects cannot be measured independently, since the transformation from prices to values depends not only on technology (the inter-industry flows) but on total consumption as well as on the sectoral consumption mix. (This is evident from Equation 5 where  $r$  and  $Z^v$  depend on  $R$ .) "Experiments" can, however, be performed by computing the rate of surplus value that would result from various combinations of these three effects. Let:

$$(xxiii) \quad Q_{ij}^a = \frac{B_{ij}^a}{Z_{ij}^a}, \quad a = 1948, 1963.$$

Let  $T^{1948}$  equal total employment in 1948 (which equals 551370) and  $T^{1963}$  equal total employment in 1963 (which equals 617987). Define:

$$(xxiv) \quad C_i^{bc} = \frac{C_i^b}{\sum C^b} \cdot \sum C^c \cdot \frac{T^b}{T^c}, \quad b = 1948, 1963, \text{ and } c = 1948, 1963.$$

$$(xxv) \quad R_{ij}^{abc} = \frac{C_{ij}^{bc}}{Z_i^a} \cdot \frac{W_j^a}{\sum W^a}, \quad a = 1948, 1963, \text{ and } b = 1948, 1963, \text{ and } c = 1948, 1963.$$

The Rate of Surplus Value in Puerto Rico  
IV. Relative Surplus Value

Eight rates of surplus are generated by:

$$(11)[1/r^{abc} - (I-(Q^a)')^{-1} (R^{abc})'] z^v = 0$$

These are shown in Table 7:

TABLE 7  
Rates of Surplus Value from  
Alternative Assumptions

	1948 Cons./Worker 1948 Cons. Mix 1948, 1948 (C )	1948 Cons./Worker 1963 Cons. Mix (C <sup>1948, 1963</sup> )	1963 Cons./Worker 1948 Cons. Mix (C <sup>1963, 1948</sup> )	1963 Cons./Worker 1963 Cons. Mix (C <sup>1963, 1963</sup> )
1948 "Tech" (Q <sup>1948</sup> )	.9729	1.1598	*	*
1963 "Tech" (Q <sup>1963</sup> )	3.8974	3.6976	1.0151	.9328

\* The 1963 level of consumption per worker would absorb more than the total gross domestic product in 1948.

The effect of technical change on the rate of surplus value becomes apparent from Column 1. If the consumption per worker and the consumption mix remained constant between 1948 and 1963, the rate of surplus would jump by 390%. This shows the tremendous effect technical change has on relative surplus value. The switch to the 1963 level of worker consumption and the 1963 consumption mix dramatically reduces the rate of surplus value to .9328. The increased consumption of labor absorbs, as

The Rate of Surplus Value in Puerto Rico  
IV. Relative Surplus Value

it were, the additional surplus generated by technical change. The effect of the change in consumption pattern is also interesting. With 1948 technology, the shift from the 1948 to 1963 consumption mix (Row 1, Columns 1 and 2) raises the rate of surplus value. With 1963 technology and 1948 consumption per worker, the shift from the 1963 to 1948 consumption mix (Row 2, Columns 2 and 1) raises the rate of surplus. With 1963 technology and 1963 consumption per worker (Row 2, Columns 4 and 3), the result is the same. The change in the sectoral distribution of consumption away from the actual distribution thus raises the rate of surplus value in the Puerto Rican case. Moreover, the change in the rate of surplus value from the shift in consumption mix is relatively small. This is probably due to the relatively small change in the consumption distribution<sup>27</sup> rather than to the insensitivity of the rate of surplus value to the pattern of consumption.

---

<sup>27</sup> The sum of the absolute values of the differences of the consumption shares is a meager .0464.

## The Rate of Surplus Value in Puerto Rico

### IV. Summary and Conclusions

#### IV. SUMMARY AND CONCLUSIONS

The startling result from this study is the relative stability of the rate of surplus value and its surprisingly high level, despite massive industrialization and the radical transformation of a society. On the basis of this result, it might be hypothesized that the rate of surplus value remains a relatively constant magnitude in a society over time (and perhaps across societies). Additional empirical work is needed to corroborate or refute this claim.

The movement of the rate of surplus value in Puerto Rico between 1943 and 1963 can be dissected into three components. First, technological change (especially the tremendous increase in productivity) dramatically raises the rate of surplus value. Second, a shift from the 1948 to 1963 consumption mix results in a slight decline in the rate of surplus value. Third, the increased level of per worker consumption in 1963 results in a sharp drop in the rate of surplus value. Thus, increased productivity counteracts the effect of increased consumption and a new consumption mix on the rate of surplus value.

Additional findings are as follows: First, the discrepancy between the rate of surplus value and the profit to wage ratio is found to be quite large. This is accounted for by the high inverse association between the sectoral ratio of value to price and the sectoral consumption share. Second, the organic composition of capital falls

The Rate of Surplus Value in Puerto Rico  
IV. Summary and Conclusions

considerably during this period of dramatic industrial change.

Third, if imports are valued according to the labor value of exports, a tremendous jump in the rate of surplus value is observed. This is accounted for by the large deficit in Puerto Rico's balance of trade and the relative import intensity of worker's consumption.

The work presented in this paper represents a first attempt at the estimation of the rate of surplus value. If appropriate data are available, refinements in the method may be made. First, differential turnover periods by sector may be included in the estimation of the rate of surplus value. Second, better estimates of the depreciation row and column may be made if capital coefficients are available. Third, a distinction between productive and unproductive labor can be drawn and its effect on the rate of surplus value determined. Fourth, different consumption patterns might be estimated for workers and capitalists. Fifth, if manpower matrices are available, adjustments might be made for different occupational groups, requiring different costs of reproduction and consuming different baskets of goods (and perhaps suffering different rates of exploitation by occupation and sector). Estimates might also be made of the "surplus" content of managerial wages. Sixth, adjustments might be made for total hours worked per year by sector, occupation and year. Data on hours per day worked, vacation time and holidays are required.
