The IZA Institute of Labor Economics is an independent economic research institute that conducts research in labor economics and offers evidence-based policy advice on labor market issues. Supported by the Deutsche Post Foundation, IZA runs the world's largest network of economists, whose research aims to provide answers to the global labor market challenges of our time. Our key objective is to build bridges between academic research, policymakers and society.

IZA Discussion Papers often represent preliminary work and are circulated to encourage discussion. Citation of such a paper should account for its provisional character. A revised version may be available directly from the author.

## ABSTRACT

---

# Overeducation Wage Penalty among Ph.D. Holders: An Unconditional Quantile Regression Analysis on Italian Data\*

The wage effect of job-education vertical mismatch (i.e. overeducation) has only recently been investigated in the case of Ph.D. holders. The existing contributions rely on OLS estimates that allow measuring the average effect of being mismatched at the mean of the conditional wages distribution. This paper, instead, observes the heterogeneity of the overeducation penalty along the wage distribution and according to Ph.D. holders' study field and sector of employment (academic/non-academic). We implement a Recentered Influence Function (RIF) to estimate an hourly wage equation and compare PhD holders who are over-educated with those who are not. The results reveal that overeducation hits the wages of those Ph.D. holders who are employed in the academic sector and in non-R&D jobs outside of the academic sector. Instead, no penalty exists among those who carry out R&D outside the Academia. The size of the penalty is higher among those who are in the mid-top of the wage distribution and hold a Social Science and Humanities specialization.

## Introduction

Investment in doctoral education is expected to lead to sizeable outcomes. From a societal point of view, it is considered a driver of economic growth since Ph.D. graduates have a high innovation potential (Auriol, 2010); from the individual perspective, instead, it is presumed to lead to private returns such as greater career opportunities as well as higher job satisfaction and wages.

Recent studies highlight that, in European countries (for Italy, Gaeta, 2015; for Spain, Di Paolo and Mané, 2016; for Austria, Schwabe, 2011; for the Netherlands, Waaijer et al., 2016) as well as in the US (Bender and Heywood, 2009), some Ph.D. holders experience overeducation once they enter the labour market, i.e. they report a vertical mismatch between the doctoral qualification acquired and the level of qualification required for the job they found (for a definition of overeducation and a survey of the literature, see Leuven and Oosterbeek, 2011). This overeducation condition might exert detrimental influence on both the societal outcomes of doctoral education - e.g. over-educated Ph.D. holders might find it hard to fully exploit their innovation potential - but it can also undermine private returns. More specifically, understanding whether this overeducation condition exerts any detrimental effect on wages is particularly important. Indeed, low private returns from doctoral education discourages enrollment into Ph.D. courses and this, in turn, might translate into inefficient selection of Ph.D. holders and lower social returns from their activity.

The limited number of studies on this topic suggests that an overeducation wage penalty among Ph.D. holders actually exists, that it is sizeable and much more substantial than the one determined by overskilling, i.e. underutilization of skills acquired during doctoral education (Sanchez and McGuinness, 2015). Focusing on US data, Bender and Heywood (2009) find that the detrimental effect of overeducation ranges between -7% and -14% of the wage of a well-matched doctor of philosophy according to the field of doctoral studies. Looking at Spanish data, Canal Dominguez and Rodriguez Gutierrez (2013) show that holding a job that does not require the Ph.D. title in the non-academic sector translates into a wage penalty that varies between -18% and -25% according to the field of study and the sector of employment. Di Paolo and Mané (2016) find a wage penalty of 11% among those Ph.D. holders from the Catalonia region of Spain who are overeducated and, at the same time, overskilled. Finally, Gaeta et al. (2017) use Italian

data and highlight that the wage gap between overeducated and well-matched doctors of philosophy ranges between -7% and -11% depending upon the specification considered.

By relying on an OLS empirical approach, the quoted papers identify the average effect of being overeducated at the mean of the conditional wages distribution; this study, instead, aims to contribute to this literature by inspecting whether there is any heterogeneity of this effect at different quantiles of the wage distribution. In other words, it aims to reveal how the wage penalty varies throughout the income spectrum of Ph.D. holders. This specific analysis provides useful insights to disentangle the relationship existing among wages, vertical mismatch and ability. Most of the empirical studies that focus on the wage penalty of overeducation are potentially biased by the omission of a reliable ability measure. Indeed, it has been noted that the possible overlapping between mismatch and low ability potentially leads to an overestimation of the impacts of the mismatch impact on wages (Kleibrink, 2016; Leuven and Oosterbeek, 2011; Verhaest and Omey, 2012). Assuming that the wage distribution reflects heterogeneity in ability, one would expect the overeducation/overskilling wage penalty to hit especially those who report low wages (McGuinness and Bennett, 2007). The approach adopted in this paper allows us checking whether this is actually true.

Having this aim in mind, this paper provides empirical elaborations based on the estimation methodology suggested by Firpo et al. (2009). This methodology uses a Recentered Influence Function (RIF) to estimate robustly a wage equation at each specific quantile that results in an unconditional quantile regression. The literature suggests that this methodology allows to overcome the limitations of the conditional quantile regression (CQR) that arise in the presence of multiple covariates (Borah and Basu, 2013). A detailed decomposition of each individual coefficient (detailed decomposition) which is exactly the case of the analysis presented in this paper. It follows that coefficients estimated by RIF are path independent and this permits an unconditional mean interpretation of the coefficient estimates that can be compared among themselves at each quantile.

To the best of our knowledge, this is the first Ph.D.-focused analysis applying such a distributional approach for examining the wage impact of overeducation.

Our analyses are based on micro-data collected by the Italian National Institute of Statistics (ISTAT) by the cross-sectional survey of Ph.D. holders, carried out in 2009. The Italian case is particularly appropriate for the aims of this paper. Ph.D. programmes were introduced in Italy in

the early 1980s when they were basically considered the main entry step for the academic career (Presidential decree 328/1980 art. 68). Few years later, in 1985, approximately 2,000 Ph.D. titles were awarded. This yearly figure increased constantly during the 1990s (approximately 4,000 titles awarded in 2000), while an impressive expansion started from the beginning of the 2000s (Ballarino and Colombo, 2010; Argentin et al., 2014), following a trend also observed in other OECD countries (OECD, 2014). In 2010 approximately 12,000 Ph.D. titles were awarded (Istat, 2015). Despite this increase in absolute numbers, compared with other countries, Italy shows a very low share of Ph.D. recipients over the working age population (OECD, 2015). Nevertheless, because of the expansion of doctoral education from the beginning of 2000s and the contemporary stagnation of academic job vacancies, a remarkable flow of doctorate holders in non-academic sectors has been observed and some concerns about the overeducation of these doctorate recipients emerged.

Not surprisingly, Gaeta (2013 and 2015) and Ermini et al. (2017) illustrate that overeducation is spread among Italian Ph.D. holders even if its incidence varies according to the field of study and the sector of employment (R&D versus non R&D). Furthermore, as already reported, Gaeta et al. (2017) use the same data used here to demonstrate that overeducation has statistically significant negative wage consequences. With respect to this latter study, this paper provides more insights into the overeducation/wage link, by providing a detailed investigation of the heterogeneity of the wage penalty along the wage distribution and by inspecting the heterogeneity across fields of study and working sectors (academic, non-academic but R&D focused, non-academic and non-R&D focused).

Such a detailed analysis allows us investigating inequality in earnings from doctoral education and the effect that job-education matching exerts on it. As a matter of fact, this provides useful information for designing policies aimed at reducing the incidence of the detrimental impact on private returns that overeducation exerts (Sánchez-Sánchez and McGuinness, 2015).

This is presumed to be particularly valuable for the Italian case but more generally valuable for the large number of countries where an increase in the number of Ph.D. holders has been recently observed (+56% doctorate degrees awarded in OECD countries over the past decade according to OECD, 2014).

The paper is structured as follows. Section 1 outlines the econometric methodology adopted. Section 2 describes the data used in the analysis and provides descriptive statistics for the main

variables. Section 3 illustrates the results achieved in baseline OLS estimates (Section 3.1) and in unconditional quantile regressions (Section 3.2). Finally, some concluding remarks follow.

## 1. Methodology

In a cross-section of data, such as those analysed in this paper<sup>1</sup>, the overeducation effect on wages can be measured, as a starting point, through an OLS estimate of the following Mincer-type earnings equation:

$$\ln w_i = \beta_0 + \beta_1 O_i + \sum_{j=1}^n \beta_j X_{ij} + \epsilon$$

Where  $\ln w$  is the natural logarithm, of net hourly wage,  $O$  identifies over-educated observations,  $X$  is a vector of  $n$  control variables, and  $\epsilon$  is the error term.  $\beta_0, \beta_1, \beta_j$  are the parameters to be estimated, with  $\beta_1$  (multiplied by 100) measuring the *ceteris paribus* percentage change of net hourly wage which is imputable to be in an overeducation condition.

Concerns about such a cross-sectional estimation strategy arise because of the potential endogeneity of  $O$ . Indeed, the value and statistical significance of  $\beta_1$  might be biased by the omission from  $X$  of any individual-level variable that simultaneously impacts on  $O$  and on  $\ln w$ . Individual ability has been suggested to potentially play the role of driver of the link between overeducation and wages (Leuven and Oosterbeek, 2011). In order to make an unbiased estimate of  $\beta_1$ , then, variables that provide a reliable and complete measure of individual ability should be included in  $X$ . The following section illustrates the wide range of individual ability proxies available in the dataset used for our elaborations that are used as regressors in our estimates in order to moderate the risk of omitted variable bias. As an alternative, an instrumental variable (IV) approach might be adopted. Finding a variable ( $Z$ ) that impacts on  $O$  but has not any other direct or indirect impact on  $\ln w$  allows to disentangle the causal relationship between overeducation and wages. Unfortunately, the literature highlights that it is very hard to find an IV able to satisfy the necessary conditions and especially the exclusion restriction, i.e. having no

---

<sup>1</sup> Unfortunately, no panel data is available.

correlation with errors in the explanatory regression. (Gaeta et al., 2017). The inspection of our data confirms this perspective.

While the OLS approach allows to observe the conditional effect of overeducation on the average wage it does not permit the inspection of the heterogeneity of this effect along the wage distribution. Nevertheless, as it has been highlighted in the Introduction, the inspection of the heterogeneity of this effect along the observed wage distribution can contribute to the identification of possible unobserved variables that drive the overeducation/wage nexus. For example, if one assumes that wages reflect heterogeneity in ability, one would expect the overeducation/overskilling wage penalty to hit especially those who report low wages (McGuinness and Bennett, 2007).

In order to capture the effect of overeducation for different levels of income, we cannot use the basic OLS estimation as the main method implemented in the literature to decompose the wage gap, namely the Oaxaca (1973) and Blinder (1973) decomposition, decomposes the gap at one point of the distribution, namely at its mean. There are several decompositions methods that allow measuring the size of the gap along the wage distribution (for surveys of this literature see, among others: Fortin et al., 2011). Most methods involve a decomposition based on the so-called conditional distribution methods. Conditional distribution methods are based on distribution regressions and can be used to compute both the composition and wage structure subcomponents of the detailed decomposition. The main limitation of these methods is computational. They require to obtain the detailed distribution of quantiles by (i) computing the different counterfactuals for each element of  $X$  and sequentially, for a large number of wage levels, and (ii) inverting to get the corresponding quantiles for each detailed counterfactual. However, this method is clearly very cumbersome and has to face a high risk of non-monotonicity, which, in turn, affects the overall estimates which is done sequentially (Fortin et al., 2011, pp. 74ff). This also means, in our specific case, that the conditional distribution method does not provide always comparable coefficients in a detailed decomposition focusing on overeducation.

To circumvent these problems, we decided to resort to the unconditional quantile regression approach (UQR) developed in Firpo et al. (2009). This method allows us to directly comparing the results of wage differences for overeducated at different (very close to each other) quantiles of the wage distribution without experiencing a path dependence in the computation of the gap

at different quantiles ([Fortin et al., 2011](#)). Being regression based, this procedure is computationally simpler to implement than the conditional one. Instead of using the conditional distribution, Firpo et al. (2009) estimate the so-called Re-centered Influence function (RIF) as a robust estimation method that regress the influence function of the unconditional quantile of our dependent variable – the logarithm of the hourly wage – on all our independent variables. Being regression based, this method is very simple to implement and to interpret. In analytical terms, for each quantile  $q_\tau$  we estimate a RIF regression which is the same as any standard regression except for the fact that the dependent variable (in our case, wages) is replaced by a recentered influence function of the statistics of interest:

$$RIF(I; q_\tau) = q_\tau + \frac{\tau - \mathbb{1}(I \leq q_\tau)}{f_I(q_\tau)} \quad (1)$$

where  $f_I(\cdot)$  is the marginal density function of  $I$  and  $\mathbb{1}$  is an indicator function. But  $RIF(I; q_\tau)$  is not observed and we have to use its sample estimate. That is

$$RIF(I; \hat{q}_\tau) = q_\tau + \frac{\tau - \mathbb{1}(I \leq \hat{q}_\tau)}{\hat{f}_I(q_\tau)}$$

And  $\hat{f}_I(q_\tau)$  is estimating using a kernel density estimation.

This method is consistent with our aims because, on the one hand, it allows us showing results at different quantiles of the earnings distribution and, on the other hand, results can be compared to each other directly. In fact, the resulting decomposition is path independent. Moreover, in contrast with the conditional quantile regression, UQR estimates show how the increase of the share of over-educated for all the population changes at a given quantile for the unconditional distribution of earnings.

## 2. Data

In 2009, ISTAT carried out an extensive nationally representative survey that involved two cohorts of doctoral recipients who had completed their graduate studies in 2004 and 2006. A more recent cross-sectional survey, carried out in 2014, is also available. Unfortunately, though,

in this more recent survey, information about Ph.D. holders' wages, which is essential for our study, is missing for a large portion of respondents (31,2%). The forced exclusion of these non-responses from the estimates has hard to predict consequences and therefore we preferred to focus our analysis on the 2009 data, also used by Gaeta et al., 2017) that do not have any severe limitation concerning data availability.

The 2009 survey carried out 8,814 interviews, of which 3,928 earned their Ph.D. in 2004 and 4,886 in 2006. The whole population of Ph.D. recipients in these two years was 18,568 (8,443 in 2004 and 10,125 in 2006; Istat, 2013) which means that the survey response rate was approximately 47%.

Ph.D. holders from all the fields of study were surveyed. Following the European Research Council (ERC) classification, the following analyses classify respondents into three study fields: Physics & Engineering (PE), Life Sciences & Medicine (LS) and Social Sciences & Humanities (SH). Consistently with CNR (2007), the 14 areas of study observed by the ISTAT survey were recoded as follows: PE includes Math, Physics & Astronomy, Earth & Environmental Science, Chemistry, Engineering, Architecture. Life Sciences and Medicine; LS includes Biological Science, Medical Science, Agriculture & Veterinary. Social Sciences & Humanities; Finally, SH includes Human Science, History & Philosophy, Law, Economics & Statistics, Political and Social Sciences. Figure 1 shows the number of observations in our sample by ERC sector and also allows us visualizing the specific study area of respondents.

[TABLE 1 ABOUT HERE]

Being focused on the link between overeducation and wages, our analysis does not consider respondents who are jobless and, therefore, do not earn any wage. As it is shown in Table 1, joblessness is reported by approximately 7% of the full sample (613 respondents) even if its incidence is definitely higher among SH doctoral graduates (8.12%) and lower among PE graduates (5.38%). These figures are definitely lower than those suggested by previous studies focused on university graduates. By observing 2004 university graduates three years after the completion of their studies, Iammarino and Marinelli (2015) find that the unemployment rate is approximately 17% in Northern Italy and 41% in Southern Italy which is definitely higher than the data observed by us. Istat (2016) states that the share of unemployment among university graduates four years after graduation is approximately 27%. Compared with these figures, our Ph.D. data suggest that completing doctoral studies is associated to an employment premium.

A further exclusion from the sample under investigation has been carried out by removing those respondents who declare to hold the same job position they held before starting their Ph.D. studies. Indeed, the overeducation question was not asked to them since they are automatically in an overeducation condition. They are a sizeable share of working Ph.D. holders, approximately 28% (2,278 respondents).

The identification of those who experience mismatch between their qualification and the job position held is based on Direct Self-Assessments (DSA). In the ISTAT survey, indeed, one question (q. 2.33) specifically asks to working respondents to indicate whether their Ph.D. title was explicitly required, at least useful or totally useless in order to get the job they carry out. On the basis of the answers to this question, a dummy variable was created that takes the value of one for those who declared that their doctorate title was totally useless. Since this question specifically focuses on the benefits arising from the Ph.D. title in order to get the job currently held (Dolton and Silles, 2008), we consider this variable as a valid measure of overeducation, according to the definition of this phenomenon reported in the Introduction. While the literature highlights that there is a number of different approaches to measure occupational mismatch (Flisi et al., 2017), unfortunately DSA is the only available one in the ISTAT dataset. The use of subjective reports by respondents exposes our analysis to the risk of measurement errors since these reports might be far from objective reality. Nevertheless, it is worth noting that “measurement error is likely to result in an underestimated overeducation penalty” (Verhaest and Omeij, 2012, p. 77) which means that our results should at least be considered as prudent estimates of the overeducation wage penalty.

Table 1 shows the overeducation figures observed in our dataset by ERC study field. Data are also displayed by sector of employment, i.e. Academia, where 46% of the employed declare to work, and outside the Academia (54%). Approximately 20% among those respondents who work, report overeducation. This figure is, of course, rather low (3.67%) when the analysis is restricted to those who work in the Academia and definitely higher (34.98%) when looking outside of it. This is not surprising since, with few exceptions (e.g. administrative and technical jobs), jobs in the Academia are supposed to require a doctorate. Table 1 reveals that those who studied LS report more frequently to be overeducation, while the lowest overeducation incidence is observed in the PE study field.

The overall overeducation figure is higher than the one observed among Italian university graduates over the same years. By analyzing a sample of graduates who completed their university studies in 2005 (old *laurea* degree, including both Bachelor and Master), Caroleo and Pastore (2017) observe that the overeducation incidence is 12,5% three years after graduation and 11.4% two years later. Nevertheless, by relying on 2005-2008 data from an Italy-based survey of active population, Aina and Pastore (2012) find that the overeducation incidence among university graduates is 19.6%, in line with our data. Compared with international data, the overeducation figure is definitely lower than the one (53%) observed in Catalonia by Di Paolo and Mané when analyzing Ph.D. holders 4/5 years after Ph.D. graduation. Schwabe (2011) shows that approximately 53% of the under 70 population of Ph.D. holders resident in Austria report that only a university degree or lower is required for carrying out their job. Waaijer (2017) state that among recently graduated Dutch Ph.D. holders, the share of overeducated is close to a quarter.

Alongside overeducation, Table 1 also reports data concerning respondents' self-reported net monthly wages. According to the available data, 5 or 3 years after the completion of doctoral studies Ph.D. holders on average earn € 1,579.63. The average median net monthly wage is 1,400 which is higher than the one reported by BA graduates in 2015 (1,283), but is exactly equal to the one observed by Master's graduated four years after the completion of their studies (Istat, 2016). Looking at Table 1, also these figures reveal some heterogeneity according to study field (PE definitely has the highest values) and sector of employment (wages are higher outside the academia).

In addition to the variables presented above, the dataset provides a wide set of information that, according to the relevant literature (Gaeta et al., 2017), are appropriate as covariates in the Ph.D. holder wage equation. These variables can be grouped as follows: i) variables related to the educational path followed before the Ph.D.; ii) variables that are related to the respondent Ph.D. studies; iv) job-related variables; v) socio-demographic variables; v) variables that observe respondents' place of residence. The detailed definition of all these covariates is presented in the appendix, in Table A.

Consistently with what has been highlighted in Section 2, it is worth noting that the covariates include some valid proxies of respondents' ability. This is the case of the following variables: i) the vote obtained at university graduation, which is presumed to depend on ability; ii) a dummy variable that observes receiving a grant for carrying out the Ph.D. studies. In the Italian academic

system these grants are normally attributed according to the results of a local competitive contest and therefore are presumed to be awarded to most able candidates; iii) dummy variables that observe having attended workshops and Summer Schools during the Ph.D. course. These kind of educational activities usually admit a limited number of students who are selected by looking at their CVs. Therefore, also in this case a positive correlation with ability is expected.; iv) one variable that measures the number of publications or patents realized since the completion of the Ph.D.. Although the dataset does not provide any information concerning the quality of these publications, it seems reasonable to suppose that other things being equal they might reveal the ability of respondents.

After the exclusion of jobless respondents and of respondents who started their current job before doctoral graduation, a sample of 5,923 respondents remains. A listwise deletion of cases reporting missing values for at least one of the variables considered, leads to a final sample built up by 5,578 observations. Table 2 presents descriptive statistics for all the variables included in the analysis. Such descriptive statistics are also reported by overeducation status.

[TABLE 2 ABOUT HERE]

Looking at the Table, the share of Academic employees is definitely higher among the well-matched (51%) than among overeducated respondents. This is in line with results from Table 1. Furthermore, the share of those whose job is at least partially focused on R&D is very high among the well-matched (approximately 83%, 63% of partially based on R&D + 20% of totally based on R&D), while it is definitely lower among the overeducated (approximately 44%, 14% of partially based on R&D + 30% of totally based on R&D). This suggests that a link exists between carrying out research-oriented duties and being overeducated. This is not surprising, since doctoral education is aimed at acquiring R&D skills and competences.

### 3. Results

#### 3.1 Baseline OLS estimates

Table 3 reports the wage penalty of overeducation as resulting from multiple log linear OLS estimates. Results calculated for the covariates illustrated in Section 2, which are all included in the models presented here, are not reported in order to save space but are available upon request. As already highlighted in Section 2, by multiplying Table 4 coefficients by 100 one would obtain the percentage change of the average net hourly wage experienced by over-educated respondents.

[TABLE 4 ABOUT HERE]

Models were estimated by relying on different subsamples. Each cell in Table 3 visualizes the wage penalty of overeducation as resulting from the analysis of a sample of Ph.D. holders that belongs to a specific field of study (PE, LS, SH or all the fields) and one specific working sector (Academia, R&D task outside Academia, non R&D task outside Academia, all sectors).

In column 1 the whole sample is considered while columns 2, 3 and 4 are respectively focused on Ph.D. holders from the PE, LS and SH study areas. This allows us inspecting the heterogeneity of the overeducation penalty determined by respondents' field of study. Recent Italian data (Istat, 2016) reveal that university graduates specialized in Social Science and Humanities report higher unemployment and lower wages than those specialized in Scientific fields (especially Medicine, Engineering Chemistry and Pharmacy). The same result is suggested by Canal and Rodríguez (2012) when analysing Ph.D. holders from Spain since they find that doctors of Philosophy in Science earn higher salaries than those in humanities and social sciences when turning outside the academic sector. The descriptive data on Italian Ph.D. holders reported in Section 3 support this scenario. Therefore, this subsamples analysis is useful in order to check whether overeducation hits harder those sectors that have lower career prospects in general and for Ph.D. holders in particular.

Each row of Table 3 identifies a specific subsample by looking at the respondents' working sector and tasks. The descriptive statistics reported in Table 3 highlighted remarkable differences in the overeducation incidence between those who work in the academic field and those who do not. Furthermore, we noted that holding a job at least partially based on R&D tasks is mainly a prerogative of non-overeducated respondents. Consistently with this descriptive evidence, this

subsamples' analysis allows to check whether overeducation hits Ph.D. holders in a different way according to their working sector and tasks carried out. In row A the whole sample is considered, in B it is restricted to those who work in the Academia, in C only those respondents who do not work in the academic field but are at least partially involved in R&D activities are considered. Finally, in row D the sample is restricted to those who hold a non-academic and non-R&D job position.

The results reported in row A of Table 3 suggest that overeducation and wages are negatively correlated ( $p < 0.01$ ). In the full sample, overeducated respondents' wage is -11.3%, which is in line with the estimates by Gaeta et al. (2017) based on 2009, data that range between -10.9% and -12.2%. Adding to previous contributions, our empirical investigation reveals that the penalty hits the SH study field (-14.6%) definitely more than the LS study field (-7.8%) while PE is in line with the value calculated on the full sample (-11.5%).

The overeducation wage penalty results to be even higher when the analysis is restricted to the academic sector of employment (row B). Ph.D.s who hold an academic job not matched with their qualification (e.g. technicians involved in labs, administrative staff, teaching position that do not imply holding a doctorate) report a penalty that ranges from -20.2%, observed for those who own a specialization in SH (barely statistically significant,  $p < 0.1$ ), and -11.5% (PE), while a not statistically significant result is found for LS.

Moving to the analysis of those who work outside the Academia, a gap between overeducated and well-matched respondents is found only among non-R&D respondents (row D). In this case, the overeducation penalty ranges between -6.5% (observed for LS,  $p < 0.001$ ) and -12.5% (SH,  $p < 0.001$ ). No statistically significant wage penalty, instead, is found when the analysis is restricted among those who work outside the Academia but carry out R&D research tasks (row C).

This result suggests that in the non-academic R&D field holding a Ph.D.-qualified job position does not translate into a wage premium. Instead, in the Academic environment, Ph.D. qualified jobs are those that are rewarded higher and the same applies to non R&D non-academic jobs.

### 3.2 Unconditional quantile regression results

In order to ease the visualization of the unconditional quantile regression results, only the estimates obtained for the overeducation variable are showed. As in the case of the OLS analysis, results for the covariates are not reported in order to save space and are available upon request. Graphical representations rather than tables are used to illustrate the heterogeneity of mismatched penalty along the quantiles of the earnings distribution.

In all the forthcoming figures, the vertical axis represents the estimated overeducation wage penalty while the horizontal axis measures quantiles of the wage distribution. The lines shown in each figure report the estimated wage penalty value as resulting from the analysis focused on the whole sample (blue line) on PE(red), LS(green) and SH (yellow). Filled dots point out statistically significant estimated coefficients ( $p < 0.1$  at least) while non statistically significant results are reported by using empty dots.

[FIGURE 2 ABOUT HERE]

Figure 2 synthesizes the results obtained for the overeducation variable when all sectors of employment are considered. Two main findings are noteworthy.

First, the detrimental effect of overeducation on wages is highly heterogeneous throughout the wage distribution. This is true when looking at the whole sample but also when looking at the estimates by study field. In some cases the penalty more than doubles when moving from one point of the distribution to another (e.g. when moving from the percentile 0.2 to the percentile 0.8). This finding confirms that the OLS estimates only allow a rough analysis of the overeducation penalty and supports the adequacy and usefulness of our analysis.

Second, although the wage penalty reported by the LS and SH sector are quantitatively different, they report a similar pattern along the wage distribution, i.e. it is flat until the fifth decile of the wage distribution, decisively increases when moving from the fifth decile onwards and, finally, drastically reduces from the eighth decile. PE, instead, shows rather constant values along the wage distribution with a notable increase in the highest end of the distribution, where a sort of glass ceiling (Maume, 1999) is observed for overeducated doctorate holders. These findings contradict the view according to which there is a strict correlation between low ability and overeducation. Indeed, a remarkable wage penalty is found among those who lay at the middle-top of the income distribution, where most able respondents are presumed to be, assuming that

wages reflects unobserved ability. This finding is definitely different from the one provided by previous contributions based on the analysis of university graduates, according to which the wage penalty of overeducation progressively reduces as the wages increase (Bender and Roche, 2017; Budria and Moro-Egido, 2008; McGuinness and Bennett, 2007).

Third, there is a remarkable heterogeneity in the size of the wage penalty of overeducation across fields of study. For most part of the wage distribution, the highest values of the penalty are observed for the SH study field. The only remarkable exception is found in the upper wage deciles (those from 0.80 onwards), when the PE study fields reports a considerably higher penalty than SH whose values turn out to be not statistically significant.

If we focus the analysis on PhD holders working in the Academia (Figure 3), we observe only slight changes of this overall picture.

[FIGURE 3 ABOUT HERE]

The highest wage penalty of overeducation is observed in the middle-top of the wage distribution for both SH - which shows the highest penalty size - and PE - which shows a penalty size only in the top of the wage distribution. A noteworthy difference with previous results is the one that concerns LS, for which no statistically significant wage gap is observed.

Moving to an analysis restricted to those who work outside the academia but hold a R&D focused job position (Figure 4) the findings are remarkably different. Indeed, a wage penalty of overeducation mostly does not arise. Indeed, statistically significant results are found only for a very limited number of quantiles and fields of study. This would suggest that once Ph.D. holders are employed in R&D duties, wages do not depend anymore on having a job in line with doctoral qualification. This is consistent with the idea that Ph.D. holders formation is specifically oriented towards R&D activities.

[FIGURE 4 ABOUT HERE]

Finally, the results obtained through the analysis of a sample restricted to those who work outside the academia and do not carry out any R&D-oriented activity, are reported by Figure 5. According to the figure, in SH and LS overeducation particularly hits wages that are in the middle of the distribution while in PE the penalty is more evident at the mid-top of the distribution. A

remarkable heterogeneity of the overeducation penalty across fields of study is observed with SH being the most penalized study field.

[FIGURE 5 ABOUT HERE]

Overall, the empirical investigation carried out allows to exploit in greater detail the heterogeneity of the overeducation impact on wages and to inspect this heterogeneity by sector of employment and by study field. In a nutshell, three main findings are noteworthy. First, an overeducation wage penalty exists among those who work in the Academic sector (where a valorisation of the Ph.D. qualification is expected) and among those who work outside the Academia but do not carry out R&D activities. Instead, no penalty exists among those who carry out R&D outside the Academia. When examining these findings, it is worth noting that the case of Academia seems less remarkable since the incidence of overeducation within Universities is very low as revealed by Table 1. Second, the size of the penalty notably varies along the wage distribution being higher in its mid-top and lower among those who earn less who might be presumed be less able. Third, SH is the ERC study field that is more hit by the penalty. PE shows striking overeducation wage penalty at the top of the wage distribution.

## Concluding remarks

The impressive increase of the Ph.D. titles awarded over the 2000s in OECD countries (OECD, 2014) has raised, in some of these countries, concerns about the doctoral graduates' career prospects (e.g. see and Gaeta et al., 2017 on Italian data; see National Center for Science and Engineering Statistics, 2015 for US data).

In line with these concerns, existing studies highlight that part of Ph.D. holders seem to be unable, at least over the first years following graduation, to find a job in line with the doctoral qualification acquired (i.e. they lay in a vertically mismatch condition). This share has been proven to be remarkable even if highly heterogeneous across countries.

This paper provided an in-depth empirical analysis of the detrimental consequences associated to this mismatch in terms of earnings. Adding to previous contributions, the paper highlighted

that i) the overeducation wage gap is highly heterogeneous along the wage distribution; ii) is particularly high in general at the mid to top end of the wage distribution, which is consistent with a glass ceiling hypothesis; and iii) this heterogeneity varies according to the Ph.D. holders' field specialization and sector of employment. More specifically, it highlights that an overeducation wage penalty is particularly remarkable among those who studied SH and among those who studied PE and lay at the top of the wage distribution. This penalty exists inside the Academia, where nevertheless the impact of overeducation is very limited, and, above all, among those who work outside the Academia but do not carry out R&D activities.

While the analysis is focused on Italian data, its results might be relevant for all the advanced economies that, just like Italy, have experienced a rapid expansion in the supply of Ph.D. holders over recent years.

In more detail, these findings contribute to the understanding of the inequality consequences associated to overeducation that might discourage brilliant students from enrolling into doctoral education. Furthermore, our results might inform the design of policies aimed at preventing the overeducation impact on wages; indeed, it allows to identify the profile (field of study/sector of employment) of those Ph.D. holders who are more exposed to the overeducation detrimental effect on wages.

In June 2011, the European Commission published the Principles for Innovative Doctoral Training stating that an active involvement of public and private entities from all the sectors in the design of Ph.D. courses. Initiatives in line with such European Union principles have been enacted also in Italy where industrial Ph.D. courses (*dottorato industriale*) have been recently established with the aim of i) creating brand new courses in agreement with the needs of private entities and ii) innovate existing courses by strengthening the collaboration with private companies. Our analysis highlights that this might be particularly important in order to provide adequate jobs outside the Academia, specifically for the SH and, to a lesser extent, for the PE study field which are those most affected by the detrimental effect of overeducation on wages.
