SOEP-Metafile.do – a Stata Do-file to Generate a Metafile for the SOEP Data Files

Klaudia Erhardt

Running since 1984, the German Socio-Economic Panel study (SOEP) is a wide-ranging representative longitudinal study of private households, located at the German Institute for Economic Research, DIW Berlin.

The aim of the SOEP Survey Papers Series is to thoroughly document the survey's data collection and data processing. The SOEP Survey Papers is comprised of the following series:

Series A – Survey Instruments (Erhebungsinstrumente)

Series B – Survey Reports (Methodenberichte)

Series C – Data Documentation (Datendokumentationen)

Series D – Variable Descriptions and Coding

Series E – SOEPmonitors

Series F – SOEP Newsletters

Series G – General Issues and Teaching Materials

The SOEP Survey Papers are available at <http://www.diw.de/soepsurveypapers>

SOEP-Metafile.do – a Stata Do-file to Generate a Metafile for the SOEP Data Files

Application of the do-file and documentation of the resulting meta file

Klaudia Erhardt

SOEP-Metafile.do

Download: <https://doi.org/10.5281/zenodo.1256001>

SOEP-Metafile.do do-file to generate a metafile for the SOEP data files.

Varlabels_Metafile.do auxiliary do-file to replace German and English metafile-variable labels.

System requirements:

The do-file was developed with Stata version 13, is adapted to the Unicode-reorientation of Stata version 14, and has been tested to run with Stata version 15.

Requires Stata IC or higher.

The SOEP website does not yet provide a DOI for downloadable software. Therefore, for the present, SOEP-Metafile.do is offered for download via the EU-funded open-science repository Zenodo.

1 Introduction and overview

This paper presents the Stata do-file SOEP-Metafile.do (version for SOEP-Users). The do-file is used to generate a summary file (metafile) of the SOEP data. To execute SOEP-Metafile.do in their local environment, users have to make only a few adjustments to the path definitions and options. Apart from this, the generation of a metafile with SOEP-Metafile.do is completely automated.

The metafile is, for its part, also a Stata file that holds data on every variable in the SOEP data files that were included in the processing by SOEP-Metafile.do. To give an impression, the figure on the next page shows a view of the metafile in the Stata data editor.

The next section describes why the metafile that is generated by the SOEP-Metafile.do is useful for SOEP users.

Section 3 explains some basic terms that are used in this paper.

Section 4 holds the detailed documentation of the metafile and its variables.

In section 5 you find the practical instructions how to generate a metafile on the SOEP data using SOEP-Metafile.do in your local environment. It describes the choices for the parameter setting and the effects they have.

Section 6 holds examples of Stata syntax to show how you can use the metafile as a basic information system on the SOEP data.

For those who are closer interested in the programming, section 7 contains a flowchart of SOEP-Metafile.do, and section 8 holds the complete syntax of the do-file.

View of the metafile in the Stata data editor

2 On the utility of a SOEP-Metafile.do-generated metafile for the SOEP data files

The SOEP is a highly complex panel study that is conducted yearly since 1984. Over the years, numerous different samples have been included. In wave 33 of the panel (data release 2017), the number of data files handed over to the users holding a data contract amounted to 440 wave specific files with 72,802 variables and 18 files of SOEPlong with 8,951 variables. The biggest file, pl, holds alone 3,170 variables.

The SOEP-Metafile.do-generated metafile is a useful support to orientate oneself in the complex data stock of the SOEP. It is an overall table of all the variables of those SOEP data files included in the generation of the metafile. Each variable of the metafile (i.e. column of the table) represents a certain characteristic of the SOEP data files or their variables, respectively. Each record of the metafile (i.e. line of the table) stands for a variable of a SOEP data file (see the view of the metafile in the figure above).

For example, the metafile-variables show how many usable observations a SOEP-variable has, how often and in which years it was surveyed, and more (see section 4, documentation of the metafile). So you can, for instance, identify with the aid of the metafile those variables of SOEPlong that are available for a certain time span, with at least X waves and with at least Y useable observations. The list of the selected variables can be used as a starting point for

searches in the SOEP information system, [Paneldata](#), in order to retrieve further information on the variables. Or it can be used in self-written do-files (see syntax examples in section 6).

Because the metafile is - like the source files processed to generate it - a Stata data file, all features of Stata to select and sort data and for reusing selected information from the metafile are available, be it within Stata or in other applications, like Microsoft Excel, that are able to read files in one of the export formats of Stata.

SOEP-Metafile.do is tuned to process SOEP data, but it does not need to be original SOEP data. The do-file can also be used to create a metafile for modified SOEP data that the user is working with.

Last, but not least, the metafile is a tool for those users of the SOEP data who have access only to Stata version IC and, thus, cannot open SOEP data files that have too many variables for Stata IC. In these cases, the metafile can be used as an information resource to select the variables for the Stata command use <varlist>, using <SOEP data file>, which is used to load subsets of data files to the working memory.

With the help of my comments in the syntax of section 8, those who are interested in the way SOEP-Metafile.do is programmed may follow the solutions I developed, such as to measure the runtime of the job or to segmentize big data files in order to reduce the runtime, using them as an incitation for self-written Stata programs.

3 Explanation of some basic terms

Some of the terms used in this paper are self-created, while others relate to SOEP-specific conditions. The following short explanations clarify their meaning in the context at hand.

Nonmissing values

The SOEP standard for missing values are one-digit negative integers, i.e. numerals between -1 and -9. Therefore, in the syntax of SOEP-Metafile.do, "non-missing values" are defined as values ≥ 0 & $< \text{sysmis}$ (see next paragraph). However, some SOEP-variables may have negative values that are not actually missing values. Mostly, these are generated income and wealth indicators. They do not receive a special treatment in the syntax, because there is no succinct algorithm to identify them.

Consequently, for those variables the number of non-missing observations is not reported correctly in the generated metafile. In most cases the concerned variables can be identified by the metafile-variable valmin (minimal value), as long as the minimal value is smaller than -9 and not equal to -200:

```
edit datenfile varname varlab valmin if valmin < -9 & valmin != -200
```

Note: -200 is a metafile-specific missing code, see section 4.2.

System missings or sysmis

Term to denominate the Stata missing codes `., .a, .b, (...) .z,` to distinguish from the SOEP-specific missing codes. The standard Stata missing code `."` is easily overlooked in the running text. Therefore, `<sysmis>` oder `sysmis` is mostly used throughout this paper.

Indicators and type 2-indicators

"Indicators" is the term used in this paper to denominate characteristics that are extracted from the source data files and their variables to be transferred to the variables of the metafile.

Type 1-indicators hold one single value for each source variable. For brevity, they are mostly called "indicators" in this paper. Type 2-indicators hold a list of values for each source variable. For example, the maximum value of a source variable is a (type 1-)indicator, while the levels of a source variable make a type 2-indicator.

In the resulting metafile, a type 1-indicator feeds a single variable and a type 2-indicator feeds a group of variables.

Macros and list macros

Within Stata syntax, macros serve as a kind of text module. In the course of a Stata program, strings or values are assigned to macros, in order to fulfil a certain task at different subsequent places in the syntax, for example as a loop counter or to transfer values to variables.

In Stata there are local macros that live only during the runtime of a Stata program and there are global macros that live throughout a whole Stata session. The complete syntax of SOEP-Metafile.do exclusively uses local macros.

In this paper, the term "list macro" is used for macros that collect a specific value for all variables of a source file, if it is about a type 1-indicator. In contrast, type 2-indicators fill a list macro for each variable and, consequently, a series of list macros for all variables of a source file.

Wave indicator

To report the survey year, different variables with different date formats were used in the numerous data files of the SOEP over the years. The actual SOEP standardized four-digit variable `syar <yyyy>` is not yet contained in every data file of the former waves. In addition, some of the SOEP data files hold divers different survey year variables.

For this reason, the applicable survey year variable of a source file is determined within SOEP-Metafile.do on the basis of a priority list that comprises the different wave and survey year variables that have been used in the SOEP. The wave indicator (metafile-variable `wind`)

reports the variable in the source file that has effectively been used to generate the survey year indicators in the meta file.

4 Documentation of the metafile

A metafile generated with SOEP-Metafile.do for the SOEP or SOEPlong data of version 33 (data release 2017) holds 261 variables: 33 flag variables for the survey years in which the source variables are present with non-missing values, 100 variables each for the levels and the values of the source variables, 18 variables reporting further indicators on the source variables, 4 variables holding indicators on the source data file, as well as 6 variables showing "technical" characteristics.

4.1 Synopsis of the metafile variables

- File related indicators
 - Number of observations in the source file
 - Number of variables in the source file
 - Number of variables in the source file with non-missing values (SOEP-specific: with values ≥ 0 & $< .$)
 - Wave indicator: relevant variable in the source file that holds the survey year
- Variable related indicators (type 1-indicators)
 - Number of non-missing observations
 - Number of system-missings
 - Number of levels
 - Number of non-missing levels
 - Value of the variable if there is only 1 level
 - Value of the variable if there is only 1 non-missing level
 - Frequency of value 0
 - Minimal value
 - Minimal non-missing value
 - Maximal value (without system missings)
 - Name of the value label definition
 - Number of unlabeled observations (only with labeled variables)
 - Highest labeled value
 - Minimal length (string variable)
 - Maximal length (string variable)
 - Number of survey years

- Earliest survey year
- Latest survey year
- Variable related type 2-indicators
 - Survey years
 - Levels (variables with max. 100 levels)
 - Value labels (variables with max. 100 levels)
- "Technical" variables
 - Consecutive number
 - Name of the source file
 - Name of the source variable
 - Data type of the source variable
 - Storage type of the source variable
 - Variable label of the source variable

4.2 Detailed documentation of the metafile-variables

Variable	Variable label	Description
lfn	consecutive number	numVar, range: integers > 0 Consecutive number of all observations. Is generated anew at each run of SOEP-Metafile.do and can therefore not be used as a unique identifier across different versions of the metafile. (A constant unique identifier for the observations of the metafile is the combination of the metafile-variables datenfile and varname)
datenfile	source file	stringVar Name of the source data file
varname	Variable name	stringVar Name of the source data variable
type	storage type	stringVar Data type of the source variable (generated by the Stata-command describe, replace clear)
isnumeric	whether numeric or string	numVar, range: 1, 0 Flag: source variable is numeric/not numeric
varlab	variable label	stringVar Variable label of the source variable. NOTE: the name of this metafile-variable can be changed by the user in the definitions-section of SOEP-Metafile.do.

Variable	Variable label	Description
nvrs	No. of vars in file	numVar, range: integers > 0
nvrsm	No. of vars in file with nonmissing values	numVar, range: integers >= 0
nobs	No. of obs. in file	numVar, range: integers > 0 Number of observations of the source data file
nonmis	No. of nonmiss. obs. (variable related)	numVar, range: integers >= 0 Number of observations of the source variable with values >= 0 & < . (numvars) or: empty and no missing code (stringvars) NOTE: not valid for variables that may have negative values that are no missing codes (mainly generated income and wealth variables). With string variables, empty entries or entries having a length of 2 characters and containing a minus sign, are evaluated as missing.
sysmis	No. of system-missing obs. (variable related)	numVar, range: integers >= 0 Number of observations with value system missing <dot>. Is invariably 0 with string variables.
uniqvals	No. of unique values	numVar, range: integers > 0 Number of unique values (including missing codes and sysmis <dot>) With string variables: Number of diverse entries (including "")
uniqvalpos	No. of unique values >= 0/nonmiss	numVar, range: integers > 0 Number of unique values >=0 & < . (thus without sysmis and missing codes) With string variables: Number of diverse entries which are neither empty, nor just 2 characters long whereof one is a minus sign (= SOEP-missing code)
valuniq	value if only 1 unique value	numVar, range: -900, -200, values of the source variable value of the source variable if uniqvals == 1 -900 uniqvals > 1 -200 with string variables
valuniqpos	value if only 1 unique value >= 0	numVar, range: -900, -200, values of the source variable Value of the source variable if uniqvalpos == 1 -900 uniqvalpos != 1 -200 with string variables
nvalzero	freq of value 0	numVar, range: integers >= 0 With string variables: frequency of empty strings
valmin	minimal value	numVar, range: -200, values of the source variable Decimals rounded to 2 decimal places -200 with string variables

Variable	Variable label	Description
valminp	minimal value ≥ 0	numVar, range: -900, -200, values of the source variable ≥ 0 Minimal value of the source variable that is ≥ 0 is (= minimal non-missing value). -900 valmax < 0 -200 with string variables
Valmax	maximal value	numVar, range: -200, values of the source variable Decimals rounded to 2 decimal places Without sysmis <dot>, except if sysmis is the only value (in that case, valmin is also sysmis) -200 with string variables
vallabset	name of valuelabel set	stringVar Name of the attached value label set "-2" no value label set is attached
undoc	No. of undocumented obs. (if var is labelled)	numVar, range: -9, -2, integers ≥ 0 Number of observations of the source variable in non-labeled categories, although a value label set is attached to the variable -9 the source variable has a value label set, but only missing codes and possibly value 0 are labeled. -2 the source variable has no attached value label set.
vlabmax	highest labeled value	numVar, range: -200, values of the source variable -200 if no value label set is attached NOTE: vlabmax relates to the defined value label set, not to actually observed categories of the source variable.
strmin	min. length (stringvars)	numVar, range: -2, integers ≥ 0 Minimal length of non-empty entries (= 0 if all entries in the source variable are empty) -2 with numVars
strmax	max. length (stringvars)	numVar, range: -2, integers ≥ 0 Maximal length of non-empty entries (= 0 if all entries in the source variable are empty) -2 with numVars
wind	wave indicator	stringVar Reports the wave indicator in the source file that is the basis for the generation of the metafile-variables nsurveys, syearmin, syearmax and sy1984 - sy20## Potential wave indicators in the source files are used according to the priority list: syear, welle, wave, intyear, erhebj, bioyear -1 the source file contains none of the wave indicators of the priority list

Variable	Variable label	Description
nsurveys	No. of waves	<p>numVar, range: -1, integers ≥ 0</p> <p>Number of waves in which the source variable is surveyed. Generated on the basis of the variables: syyear, welle, wave, intyear, erhebj, bioyear (rank order, the first met variable is used)</p> <p>0 the source file contains a wave indicator, but the source variable has no non-missing values</p> <p>-1 the source file contains none of the wave indicators of the priority list</p>
syyearmin	earliest survey year	<p>numVar, range: -9, -1, integers ≥ 0 & \leq survey year of the actual data release</p> <p>Earliest year in which the source variable was surveyed, i.e. minimal value of the relevant wave indicator, without transformation into the four-digit format yyyy</p> <p>-1 the source file contains none of the wave indicators of the priority list</p> <p>-9 nsurveys == 0 (i.e. the source file contains a wave indicator, but the source variable has no non-missing values)</p>
syyearmax	latest survey year	<p>numVar, range: -9, -1, integers ≥ 0 & \leq survey year of the actual data release</p> <p>Latest year in which the source variable was surveyed, i.e. maximal value of the relevant wave indicator, without transformation into the four-digit format yyyy</p> <p>-1 the source file contains none of the wave indicators of the priority list</p> <p>-9 nsurveys == 0 (i.e. the source file contains a wave indicator, but the source variable has no non-missing values)</p>
sy1984 - sy20##	--	<p>numVars, range: -1, 0, 1</p> <p>Flag variable for the presence of the source variable in the survey years</p> <p>1 the source variable has nonmissing values in the survey year</p> <p>0 the source variable has not been surveyed or has no non-missing values in the survey year</p> <p>-1 the source file contains none of the wave indicators of the priority list</p>

Variable	Variable label	Description
val1 - val100	--	<p>numVars, range: -200, -100, -900, sysmis, values of the source variable</p> <p>The variables val1-val100 show the values of the actually observed levels of the source variables (only variables with maximally 100 non-missing levels</p> <p>-100 numVar has more than 100 non-missing levels</p> <p>-900 numVar has maximally 100 levels, but all values are < 0 (SOEP-missing Codes)</p> <p>-200 stringvars. (The values of the stringvars are recorded in the metafile-variables lab1-lab100, because val1-val100 are numvars and cannot hold strings)</p> <p>sysmis <dot> val#-variables that are not taken</p>
lab1 - lab100	--	<p>strVars</p> <p>The variable lab1-lab100 show the labels of the actually observed levels of the source variables (only variables with maximally 100 non-missing levels</p> <p>"###" level without label, although the source variable has value labels (= undocumented levels, or scales where only the endpoints are labeled)</p> <p>"-100" source variable has more than 100 non-missing levels</p> <p>"-200" source variables without attached value label set</p> <p>"-900" source variable has value label set and maximally 100 levels, but all values are < 0 (SOEP-missing Codes)</p> <p>With string variables the metafile-variables lab# hold the unique values (levels) of the source variable.</p>

5 How to generate a metafile on the SOEP data using SOEP-Metafile.do

To generate a metafile on the SOEP data, users must adapt the do-file SOEP-Metafile.do to their local environment. What has to be done in practice, is described in detail in section 5.2 of this paper.

Before that, some insight into the functioning principles of SOEP-Metafile.do shall be provided, which will make it easier to understand the parameters that have to be set:

SOEP-Metafile.do uses all - or a selection of - the Stata data files that are stored in a directory that has to be determined by the user. These data files are processed one by one, while certain indicators for the variables in the data files are extracted. The indicators for all the variables of a specific data file are saved temporarily in a file-specific metafile. After the data files are processed, the file-specific metafiles are assembled to the overall metafile, which is the final outcome.

To minimize the runtime of the job, data files holding more than a certain number of variables are fractionised into smaller portions (sectionized processing).

In the output and appointed log files, SOEP-Metafile.do reports the advancement of the process, possible data problems preventing the processing of a file, the name and path of the resulting metafile, as well as the runtime of the job.

5.1 Hints and recommendations on the use of SOEP-Metafile.do

- The runtime of SOEP-Metafile.do in the EDV-environment of the SOEP FDZ¹ was a short hour for the wave specific SOEP files and about 3 hours for SOEPlong (data release v33, 2017), with sectionized processing and data portions of 50 variables.
- In view of the runtime, the correct functioning of SOEP-Metafile.do should be tried out in a test run. This can either be achieved by specifying a criterion in the macro files that is met only by few data files (such as: `bgp*.dta`, `*kind.dta` etc.). Or by setting up a test directory that contains only certain data files. For test runs on the big SOEPlong data files, it is highly recommended to reduce the number of observations in the files drastically, because the number of observations influences the runtime to a high degree.
- It is more efficient to generate separate metafiles for the wave-specific SOEP-files and for SOEPlong. Because, if you generate one metafile for both in one single run of SOEP-Metafile.do, the resulting file will hold records on SOEP-variables and on SOEPlong-variables, but no concise criterion to separate both if necessary is available. If you wish to have one single metafile for both data pools, you should generate them separately and

¹ FDZ: Forschungsdatenzentrum (Research Data Center)

join the two metafiles by the Stata command `append, generate(newvar)`. This procedure generates a flag-variable that signals the origin of the records as either from SOEP or from SOEPlong.

5.2 Adaptations required in the syntax segment "Definition of parameters"

The syntax of SOEP-Metafile.do is divided in several sections. Adaptations by the users are made exclusively in section "B) DEFINITION OF PARAMETERS", which follows section "A) AUTOMATIC DEFINITION OF PARAMETERS". Comments and examples that are inserted into the syntax help with the determination of the parameters.

Further modifications of SOEP-Metafile.do are not required and should only be made if you have an in-depth understanding of the procedures of the do-file.

In section "B) DEFINITION OF PARAMETERS" the macros are defined, which are listed in the following table. The indication "mandatory" means: the macro must not be empty but has to hold a value (i.e. the macro may not be defined as: `local xyz ""`). In contrast, optional macros may be defined as empty. The respective consequences of that are described in the table. The indication "optional, or mandatory if SYI desired" means: The macro is optional if no survey year-indicators (SYI) are desired. However, if SYI are desired, the macro must hold the appropriate value.

Most of the listed macros in the table are either defined by a default value if they have not been defined in the section "definition of parameters", or if they are already predefined in the section "definition of parameters" and either may be changed or may as well stay unchanged. Thus, the number of parameters that must be set by the user is diminished considerably, compared to the list.

In the table, the parameters that must be set by the users are highlighted in yellow. Alongside these, there are parameters highlighted in pale blue, which must be controlled by the user and, if necessary, adapted.

Name of the macro	Explanation
we	<p>Appendix to the name of the resulting metafile. Ought to be used to indicate the SOEP version that is used to generate the metafile.</p> <p>Optional. If the macro is defined as empty, the file name of the resulting metafile does not show the version of the SOEP data it is based on. In addition, the metafile of the previous run is overwritten unintendedly, if the actual metafile is generated in the same day and written to the same target directory (e.g. if you generate metafiles for the wave specific SOEP data and for SOEPlong).</p> <p>Predefined in the syntax as "_SOEPv33_long".</p> <p>Recommendation: Control and, if necessary, adapt the macro definition.</p>
data	<p>Path of the directory where the SOEP data files that are to be processed are stored.</p> <p>Mandatory. Note: The source files are loaded to the working memory. No changes to the original data are made, therefore there is no risk of data loss by using SOEP-Metafile.do .</p>
pfad1 pfad1d pfad1o	<p>pfad1d: Target directory for the resulting metafile pfad1o: Target directory for the logfile both are subdirectories to the target main directory pfad1.</p> <p>Mandatory. The path specifications are designed to fit the common practice to establish separate subdirectories to a main directory for data, output, and do-files (the latter not being used by SOEP-Metafile.do. All 3 macros must hold path definitions, but it is allowed to supply the same path to them (see examples in the syntax).</p>
files	<p>Criterion to select the files that are to be processed within the source directory. The criterion must consist of a single item with or without wildcards, i.e. "bdp.dta" or "b*.dta" or "*p.dta").</p> <p>Optional. If the macro is defined as empty, the default value "*.dta" is used.</p>
port	<p>Number of variables per portion with segmented processing.</p> <p>Optional. If the macro is defined as empty or has the value 0, the default value 50 is used. This value has proved to be a good trade-off between reducing the runtime by segmentized processing and augmenting the runtime by a higher number of runs over the portions.</p> <p>Note: If the value of port is bigger than half the number of variables in a file, the file is processed without portioning.</p>
varlab	<p>Name of the variable in the metafile holding the variable labels of the source variables.</p> <p>Optional. If the macro is defined as empty, the default-value "varlab" is used.</p> <p>The purpose of this macro is to hold English and German variable labels in the same metafile. If the runtime is no problem, you can generate a metafile for the English and German SOEP data versions each, and then merge the label of the other language to the master metafile using the key variables datenfile and varname.</p>
result	<p>Name of the resulting metafile. Predefined as: metafile`we'`datum'.</p> <p>Mandatory. It is allowed, but not required, to change the macro definition.</p> <p>Recommendation: Do not change the predefinition of the macro.</p>
reslab	<p>Label that is attached to the resulting metafile using the Stata-command label data.</p> <p>Optional. If the macro is defined as empty, no label is attached to the metafile.</p>

Name of the macro	Explanation
lg	Name of the resulting log file. Defined as: metafile`we'`datum'.log. Mandatory. It is allowed, but not required, to change the macro definition. Recommendation: Do not change the predefinition of the macro.
syrlst	Priority list of the possible wave indicators in the source files. Predefined as: "syear welle wave intyear erhebj bioyear". Optional, or mandatory if SYI desired. It is allowed, but not required, to change the list. Changes in the rank order of the list are not reasonable. The macro may be defined as empty. This has the consequence that the resulting metafile holds no information on the appearance of the variables in the survey years. Recommendation: Do not change the predefinition of the macro.
wave1, wave2	Earliest and latest survey year, predefined as wave1 = 1984, wave2 = 2016 (= current wave of V33). Optional, or mandatory if SYI desired. The macros may stay empty if no information on the survey years is desired. If survey year indicators are desired, wave2 has to be adapted to the current wave, while wave1 stays unchanged. Note: wave1 and wave2 are also used in the syntax to discriminate valid and invalid survey years. Therefore the definition of wave1 and wave2 ought to conform with the actual earliest and latest waves in the SOEP data, if not empty. Recommendation: Don't change the predefinition of wave1. Control and, if necessary, change wave2.

6 Syntax examples on how to use the metafile

Note: In the following, i.a. string functions for data selection are presented. From Stata 14, the names of string functions have a prefixed "u" (standing for "Unicode"). The function `strpos()` becomes `ustrpos()` with Stata 14, for instance. Therefore, if you are using Stata 14 or higher, the syntax examples must be adapted accordingly.

To write syntax that works both with Stata 13 and higher Stata versions, you can define a macro that is prefixed to the function name and that contains a "u" if Stata from version 14 is the current program and is empty otherwise. You can see in the SOEP-Metafile.do-syntax in section 8 how this is implemented practically.

As far as the following examples relate to concrete data, they have been made with data from a metafile generated from SOEPlong v33 (data release 2017).

Regrettably, the examples in this documentation, the English language version, use data with German variable labels. Please accept my apologies: rerunning the examples in English would have consumed a significant amount of time.

6.1 Create views of the metafile in the Stata data editor

Using the Stata data editor, the metafile can be viewed literally as a table. Using the edit mode, you can change values manually or copy them to the clipboard, while the browse mode only allows for looking at the data. In any case, it is much more comfortable for a human viewer to restrict the displayed information to the data that is currently relevant.

6.1.1 Selection of metafile-variables

If you want to view certain variables from the metafile, it is often advisable to define narrower display formats before editing or browsing, so that more columns fit into the screen area:

```
format lfn %6.0g
format datenfile varname %8s
format varlab %46s
format nonmis uniqvalpos valminp valmax nsurveys syearmin syearmax %6.0g
format sy1984-sy2016 %7.0g
edit lfn datenfile varname varlab nonmis uniqvalpos valminp valmax nsurveys
syearmin syearmax sy1984 sy1985 sy1986
```

6.1.2 Selection of observations

```
edit <varlist> if <conditions>
```

or:

```
browse <varlist> if <conditions>
```

The Stata expressions to select string variables are less known than the ones to select numeric variables. As the metafile contains quite a few string variables, the most important string functions for data selection are presented by the following examples.

- ... if the string "erwerbs" is contained in varlab:

```
...if strpos(varlab, "erwerbs") > 0
```

The function `strpos()` returns the value 0, if the sought after string is not contained within varlab.

- ... if the string "erwerbs" or "Erwerbs" is contained in varlab:

```
...if strpos(strlower(varlab), "erwerbs") > 0
```

In this example the string functions `strpos()` and `strlower()` are nested. The expression signifies: ... if the string "(...)" is contained in varlab after the transformation in lower case characters (equivalent to: no matter if it is put in upper or lower cases).

- ...if the variable contains a string that begins with "bgp":

```
...if strpos(datenfile, "bgp") == 1
```

or:

```
...if substr(datenfile, 1,3) == "bgp"
```

The first version asks if the string "bgp" begins at the first position of the content of variable datenfile. The second version asks if three characters of the variable content, beginning with the first character, are made out of "bgp".

See more details and further string functions using the Stata command help string functions.

6.2 Selection of variables from the SOEP Long-files

For a still not precisely outlined research project, the SOEPlong data can - as an example - be explored for variables that have been surveyed in at least 5 waves since 2008 and that have at least 500 non-missing observations. The successive examples show a (simplified) process of concretisation of the final research issue.

Attention: Potential pitfall! You might be tempted to put the condition as follows:

```
... if syearmin >= 2008 & nsurveys >= 5
```

This would be wrong, because the condition excludes those variables that comply with the above named requirements, but were also surveyed in waves before 2008.

Instead, we generate an auxiliary variable that indicates how often a variable has been surveyed since 2008:

```
capture drop h1
egen h1 = anycount(sy2008-sy2016), values(1)
```

Thereafter, the auxiliary variable h1 can be used to express the selection criterion:

```
ed lfn datenfile varname varlab nonmis nsurveys syearmin syearmax if h1 > 4 &
nonmis >= 500
```

→ This condition is met by 1,949 variables in SOEP long (V33).

A visual inspection shows that the selected set contains variables relating to "satisfaction". These shall be examined closer (note: "Zufriedenheit" is the German word for "satisfaction"):

```
ed lfn datenfile varname varlab nonmis h1 if strpos(varlab, "ufriedenh") > 0 &
nonmis >= 500
```

→ the selected set contains 5 variables from the file jugendl and 12 variables from the file pl. We decide on using only data from pl, but we need to investigate if there are further satisfaction-related variables in pl that were excluded by our selection criterion. In any case, we want to hold on to the criterion "at least 500 non-missing observations". However, we lower the number of waves in which the variables have been surveyed within the relevant period to at least 1:

```
ed lfn datenfile varname varlab nonmis nsurveys syearmin syearmax h1 if datenfile
== "pl" & nonmis >= 500 & h1 > 0 & strpos(varlab, "ufriedenh") > 0
```

To define macros for the repeatedly used components is a more elegant way to deal with long Stata commands:

```
local vars "lfn datenfile varname varlab nonmis nsurveys syearmin syearmax h1"
local cond "datenfile == \"pl\" & nonmis >= 500 & h1 > 0"

ed `vars' if `cond' & strpos(varlab, "ufriedenh") > 0
```

→ This condition results in a set of 37 variables. We sort these according to how often they were surveyed during the relevant period. Our second sort criterion is varname, because variables belonging to the same item set usually have consecutive variable names in the SOEP data:

```
sort h1 varname
```

After inspection in the data editor, we decide to use the previously selected satisfaction-variables, which have been surveyed 9 times in the relevant period, plus the 4 variables that were only surveyed in 2016 and that measure the "satisfaction with [...] in the last 10 years (German variable label: "Zufriedenheit mit [...] in den letzten 10 Jahren"). We mark these variables with a flag variable (see next section).

6.3 The use of an auxiliary variable to mark selected variable sets

It may be difficult or even impossible to retrieve a certain variable set using a concise selection criterion. For example, the applied selection criterion may retrieve - besides the desired hits - some variables that do not belong to the targeted set. Or otherwise, the selection criterion is already very complex and you need to add further conditions. In such cases you can generate a flag variable that marks if a variable belongs to the targeted set. The flag can be set or unset stepwise.

While it is possible to change the flag variable manually in the data editor, it is strongly recommended not to do so. Instead, executing every step using the Stata syntax editor and saving the steps to a sps-file, makes your data preparation reproducible.

To continue the above example:

First, we test with edit if the selection criterion is correct and leads to the targeted variable set:

```
local vars "lfn datenfile varname varlab nonmis nsurveys syearmin syearmax h1"
local cond1 "datenfile==\"pl\" & nonmis >= 500 & strpos(varlab, \"ufriedenh\") > 0"
local cond2 "h1==9 | (h1==1 & syearmax==2016 & strpos(varlab, \"letzte 10\") > 0)"

ed `vars' if `cond1' & `cond2'
```

After that we use it to generate the flag variable:

```
capture drop f1
local cond1 "datenfile=="pl" & nonmis >= 500 & strpos(varlab, "ufriedenh") > 0"
local cond2 "h1==9 | (h1==1 & syearmax==2016 & strpos(varlab, "letzte 10") > 0)"
gen f1 = cond(`cond1' & `cond2', 1, 0)
```

alternatively, if you are not familiar with the cond() syntax:

```
capture drop f1
local cond1 "datenfile=="pl" & nonmis >= 500 & strpos(varlab, "ufriedenh") > 0"
local cond2 "h1==9 | (h1==1 & syearmax==2016 & strpos(varlab, "letzte 10") > 0)"
gen f1 = 0
replace f1 = 1 if `cond1' & `cond2'
```

Recommendation: control the result always with edit if f1==1

We notice an odd gap between lfn 7520 (Variable plh0180) and lfn 7522 (Variable plh0182). Why did our selection criterion not retrieve the variable in between with lfn 7521? (Note: if you have not dropped any observations, the variable lfn contains a consecutive number without gaps).

```
local vars "lfn datenfile varname varlab nonmis nsurveys syearmin syearmax h1"
local cond1 "datenfile=="pl" & nonmis >= 500 & strpos(varlab, "ufriedenh") > 0"
local cond2 "h1==9 | (h1==1 & syearmax==2016 & strpos(varlab, "letzte 10") > 0)"
ed `vars' if (`cond1' & `cond2') | lfn == 7521
```

→ We see the reason why the variable was excluded: it was surveyed in the relevant period only 4 times, instead of 9 times like the adjacent variables. One of our condition was: h1 == 9 or (h1 == 1 and (...)). If we decide on including this variable in the target set, we mark it in the flag variable f1:

```
replace f1 = 1 if lfn == 7521
```

As a rule you should examine thoroughly if the result is in accord with the desired target set. This is most important if the variable label is part of the selection criterion and if you do not explore SOEPlong variables but wave specific variables. Typing errors and other irregularities may easily prevent a variable that belongs to the target set from being included in the selected set.

It is also highly recommended to have a look at the variables that neighbour the finally selected variables in order to identify and find those variables that do not meet the selection criteria but belong semantically to the selected set (as was the case in the above example). For instance, rarely stated items from item sets or variables that mark the overall-non-response of an item set may easily fall through the selection grid. The easiest way to find neighboured variables is by adjacent values of lfn.

The variable selection to date has the running numbers (lfn) 7511 through 7522 and 7676 through 7679. We use these to view the adjacent variables:

```
sort lfn
local vars "lfn datenfile varname varlab nonmis nsurveys syearmin syearmax h1"
edit `vars' if (lfn > 7505 & lfn < 7528) | (lfn > 7670 & lfn < 7685)
```

→ We can see that there are no variables that belong directly to our set of selected variables. However, we see variables on the frequency of certain emotions in the last 4 weeks. We add these to our selection set ("letzte 4" is "last 4" in German):

```
local cond3 "(lfn > 7505 & lfn < 7528) | (lfn > 7670 & lfn < 7685)"
replace f1 = 1 if (`cond3') & strpos(varlab, "letzte 4") > 0
```

Please note the additional brackets that enclose `cond3' in the replace-command. Without these, Stata would interpret the condition as follows: Either lfn lies between 7505 and 7528 OR lfn lies between 7670 and 7685, and the string "letzte 4" is found in varlab. This is not what we want. We want the instruction "letzte 4" is found in varlab to be applied to both number ranges.

This is another instance of how important it is to carefully verify that the applied commands return the desired results.

Thus, after the desired variable set is defined, in the next section you will see how a list of the selected variables can be created for use in self written syntax.

6.4 How to capture the selected variable names for further uses

To capture the names of the selected variables, we use the Stata command `levelsof`, which returns the levels of variables, since the names of the SOEP-variables are levels of the metafile-variable varname:

```
quietly levelsof varname if f1 == 1, clean local(vars)
global myvars "`vars'"
display "${myvars}"
```

The first line of this command sequence assigns the variable names to the local macro vars. The option `clean` causes the suppression of the quotation marks that would otherwise surround the variable names in the list.

The command `levelsof` can assign levels of variables to local macros only. In order to keep the variable list available during the complete Stata session, it is assigned to the global macro `myvars` in the second syntax line.

To work with the variables of this list, further variables, like IDs and weighting factors, are needed. Absolutely necessary are the key variables that serve as unique identifiers for a case in the source files - with `SOEPLong`, these are `pid` and `syear`. Either the additional variables can be marked in the flag variable, as shown above, or you add it to the list, as shown in the syntax below.

```
quietly levelsof varname if f1 == 1, clean local(vars)
global plmyvars "hid cid pid syear `vars'"
```

Note: the weighting factors (in German: Hochrechnungsfaktoren, Abbreviation hrf) can be retrieved in the wave specific files as well as in SOEPlong by the criterion if `strpos(varname, "hrf") > 0`. In SOEPlong, these are located in the data files `hpfad` und `ppfad`. Therefore, they cannot be included into the above compiled list, which is used to select variables from a single SOEP data file. How to proceed if the needed variables are located in different data files, is described in section 6.5.

This is how you use the variable list to retrieve the selected variables from the SOEPlong file `pl`:

```
use ${plmyvars} using pl, clear
```

6.5 Proceeding if the selected variables are located in several data files

The easiest way to do this is to define a separate list for each data file, either as described above or manually. It is recommended to flag the related data file and possibly the content in the name of the list, in order to not confuse the lists:

```
global hrfppfadl "phrf phrfe"
```

This list of the weighting factors and the above defined list `plmyvars` are then used to merge the needed variables into a target data file:

```
use ${plmyvars} using pl, clear
merge 1:1 pid syear using ppfadl, keepusing ${hrfppfadl}
```

If the needed variables are located in a multitude of data files, as may often be the case with wave specific files, you would generate a flag variable in the metafile and mark all the needed variables, no matter in which data file they are located, in exactly the same way as described above.

After that you generate a list of the related data files with the command `levelsof datenfile...`. In a second step this list is used to generate the file-specific variable lists (for example). For this, the procedure loops over the entries in the list of data files. The counter of the loop is obtained from the number of entries in this list. The metafile is still the active data set, `f1` is the flag variable for the needed variables:

```
quietly levelsof datenfiles if f1 == 1, clean local(files)
global myfiles "`files'"
local nf : word count `files'
forvalues i = 1(1)`nf' {
    local f : word `i' of `files'
    quietly levelsof varname if f1==1 & datenfile == "`f'", clean local(vars)
    global `f'vars "`vars'"
}
```

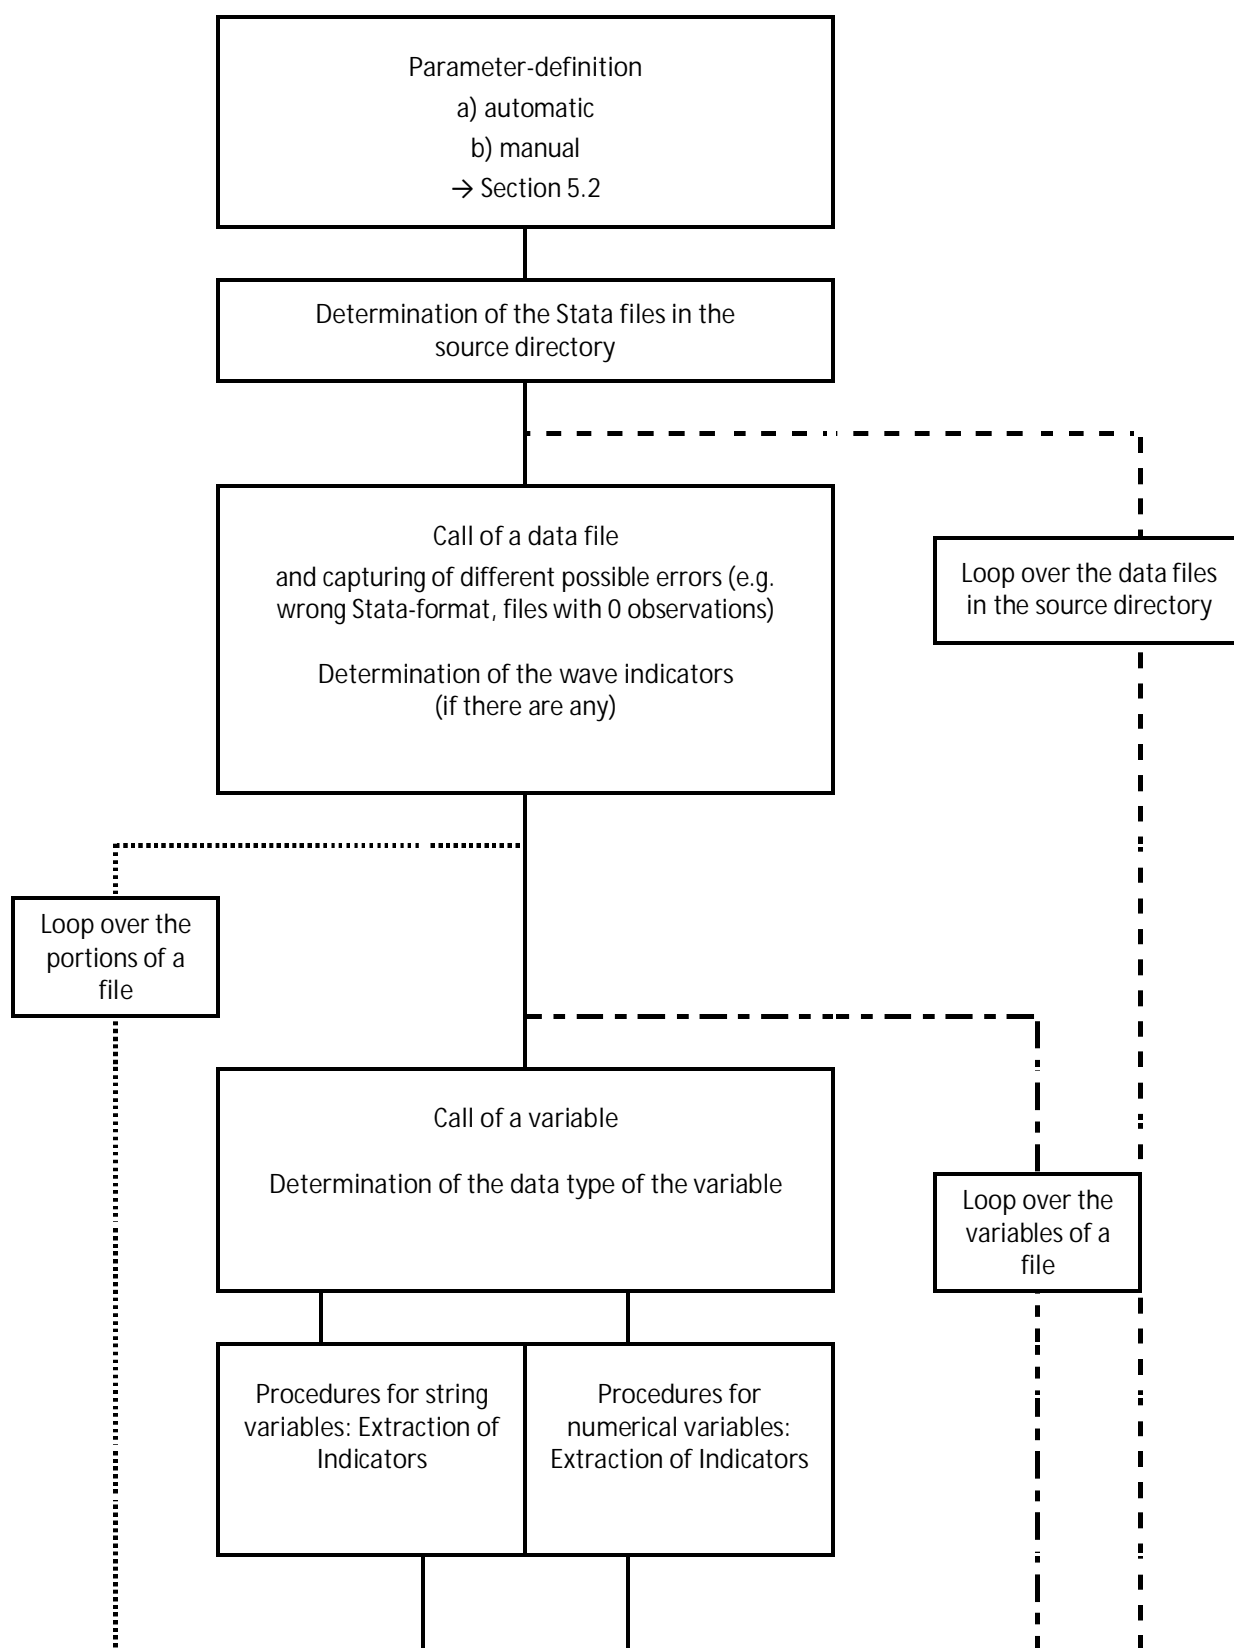

In this syntax sequence, the variable lists in local macros, which have been generated with `levelsof varname`, are copied to global macros so that they are still available after the

execution of this commands. In the same step, the variable lists are renamed to a data file-specific name.

To continue, the metafile is no longer needed because all relevant information has been transferred to macros. Therefore, the file specific variable lists can be used to compose the commands to call the related data files and do whatever you want to do for your analyses. However, note that the data file list contains the pure file names, without paths, which have still to be added in the commands.

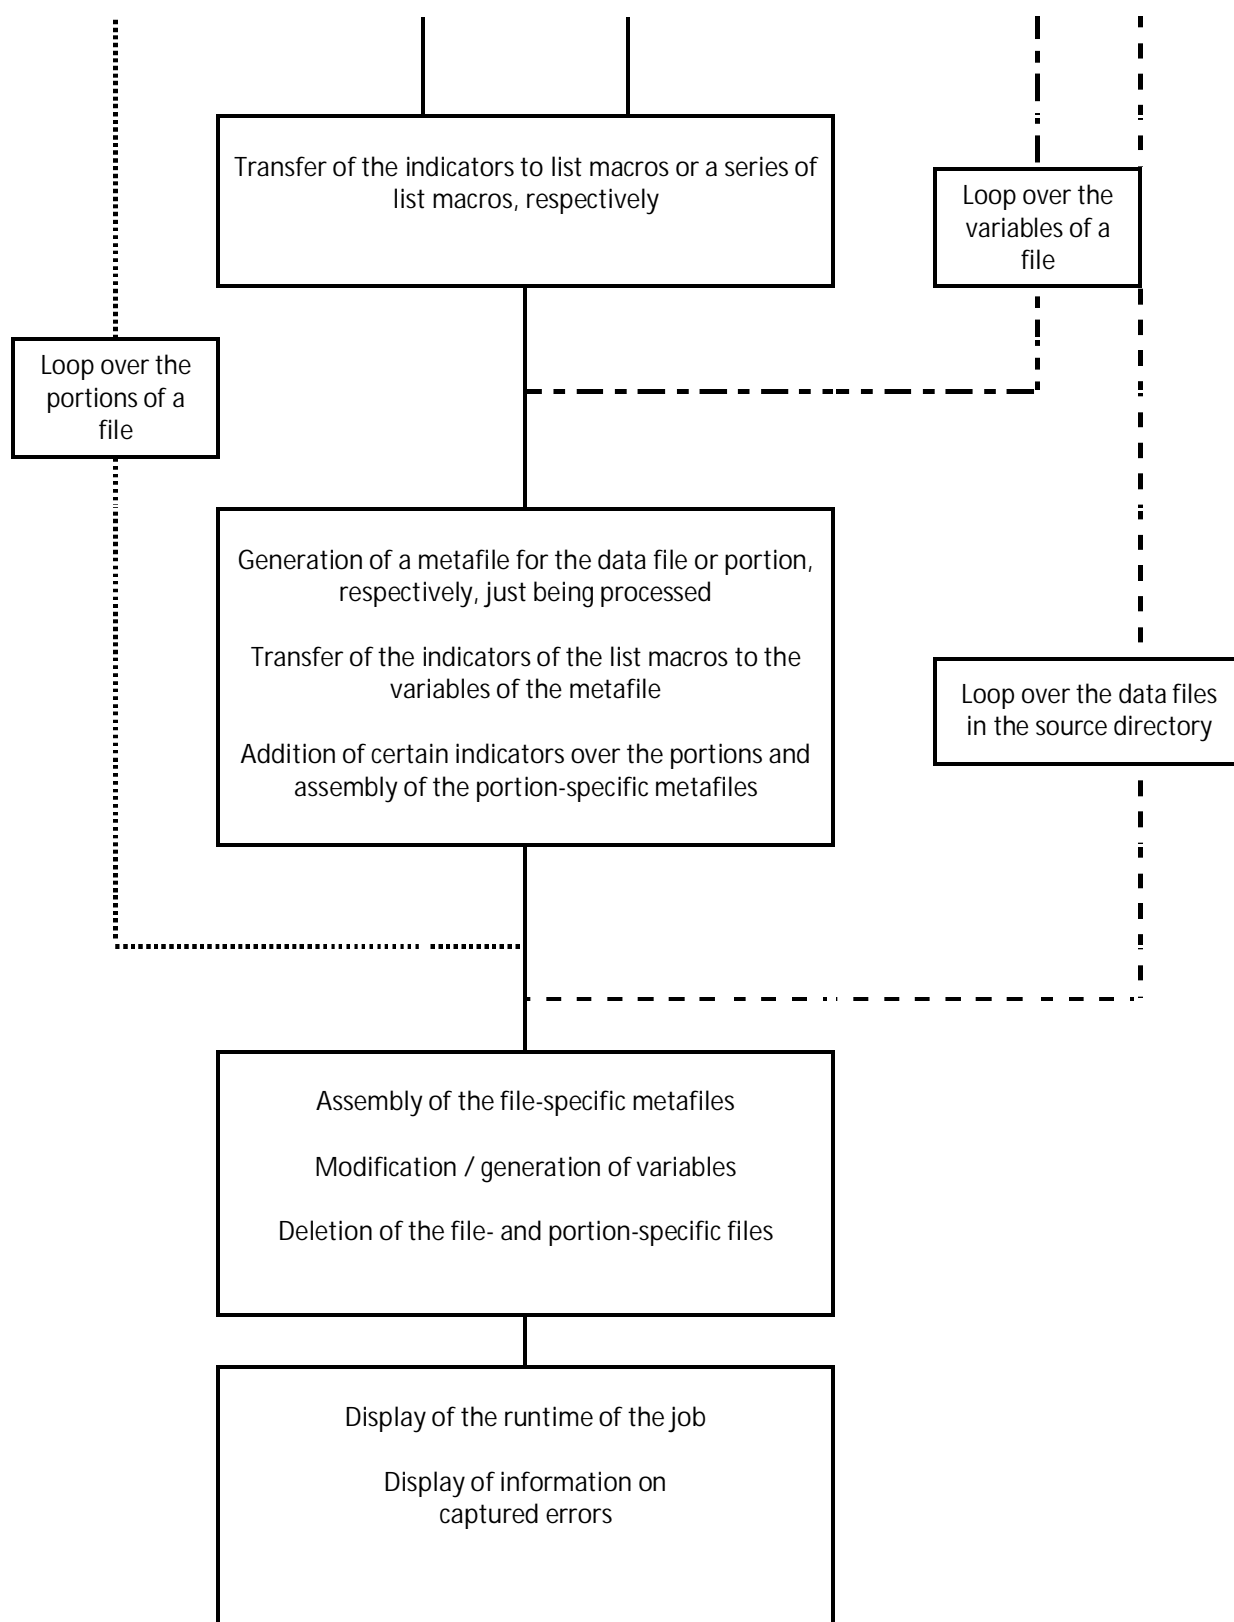

The syntax examples of this chapter are intended to guide further uses for variable and file lists that are generated from the metafile. For example, you could write syntax to automatically generate and save do-files. However, the paper at hand does not go deeper into this procedures.
