Nº 61

POLÍTICA SALARIAL, INFLAÇÃO E SALÁRIO REAL:  
UM EXERCÍCIO DE SIMULAÇÃO\*

Francisco L. Lopes

---

\* Pesquisa financiada pelo Programa Nacional de Pesquisa Econômica, PNPE. O autor agradece a assistência de Ricardo Luis de Lima Vianna.

## 1. Introdução

Este trabalho apresenta exercícios de simulação quantitativa das consequências inflacionárias e distributivas de diversas alternativas de política salarial. O objetivo é obter tanto um entendimento qualitativo dos fenômenos estudados como uma avaliação da magnitude relativa destes efeitos.

A próxima seção discute a base empírica das simulações, a seção 3 apresenta o modelo utilizado, e as seções seguintes discutem os resultados obtidos.

## 2. Base Empírica

Este exercício de simulação baseia-se numa versão do modelo de determinação de preços e salários desenvolvido em Lopes (1982). Supondo que:

$p_i$  = IPA-DI, produtos industriais

$p_o$  = preço do óleo combustível

$p_m$  = preço em cruzeiros das importações totais

$w$  = índice utilizado nos reajustes-salariais (igual ao INPC a partir de 1980, estimado pelo autor para período anterior)

---

\* Pesquisa financiada pelo Programa Nacional de Pesquisa Econômica, PNPE. O autor agradece a assistência à Pesquisa de Ricardo Luis de Lima Vianna.

$c_w$  = custo da mão de obra

U = hiato de produto, indústria de transformação

a versão estimada do modelo foi a seguinte:

$$(1) \quad \hat{p}_i = a_1 \hat{p}_o(-2) + a_2 \hat{p}_m(-2) + a_3 \hat{c}_w - a_4 U + a_5$$

$$(2) \quad c_w = \sum_{k=0}^{k=n} w(-k)$$

$$(3) \quad \hat{w}(+2) = b_1 \hat{p}_i + b_2 \hat{c}_w$$

A equação (1) determina os preços industriais em função do preço do óleo combustível, do preço dos insumos importados, do custo da mão-de-obra e do nível de atividade na indústria de transformação. A equação (2) define o custo da mão-de-obra como a média aritmética dos índices de reajuste salarial defasados n períodos, sendo n o período legal das correções salariais. Isto equivale a supor uma distribuição uniforme dos trabalhadores por data de reajuste: a cada mês, uma fração 1/n da força de trabalho tem um aumento salarial. A equação (3) define o índice de correção salarial em função dos preços industriais e do custo de mão-de-obra defasados dois períodos. Esta defasagem corresponde à prática atual de aplicar o INPC defasado em dois meses nos reajustes salariais. Pode-se notar que o modelo é idêntico ao modelo utilizado em Lopes (1982) com a hipótese de elasticidade de substituição unitária entre óleo combustível, insumos importados e trabalho na equação (1).

Os resultados de regressões das equações (1) e (3) são apresentados nas Tabelas 1 e 2, usando observações mensais e trimestrais entre 1974 e 1982. (Note, porém, que todas as taxas de variação são taxas de doze meses). Com base nestes resultados adotamos os seguintes valores dos coeficientes nas nossas simulações:

$$a_1 = 0,10; a_2 = 0,20; a_3 = 0,70; a_4 = -0,5; a_5 = -0,01$$

(baseados na estimativa 5) e:

$$b_1 = 0,5; b_2 = 0,5$$

### 3. O Modelo de Simulação

O modelo de simulação foi derivado das equações (1), (2) e (3). A base de todas as simulações é um sistema com recomposição dos picos de salários reais e periodicidade semestral. Neste caso podem ser identificados seis classes de trabalhadores, diferenciados pelo mês de reajuste, que indicamos por  $w_j, j=1, \dots, 6$ . Além disso supõe-se que:

$$\hat{p}_0 = \hat{p}_i$$

$$1 + \hat{p}_m = (1 + \hat{p}_i)(1 + \hat{e})$$

onde " $\hat{e}$ " é a taxa de desvalorização real da taxa de câmbio, uma variável exogenamente determinada.

| 4 - | 74-04 a<br>79-07 | Trimestral         | 0,571<br>(3,29)      | 0,429                      | 0,63           | 1,61 | 0,034<br>(0,79) |

(\*) Coeficiente não estimado. A regressão foi restringida pela hipótese de soma unitária dos dois coeficientes.

Em todos os casos são usadas as seguintes equações:

$$(4) \quad \hat{p}_i = 0,10 \hat{p}_i(-2) + 0,20 (1 + \hat{p}_i(-2)) (1 + \hat{e}(-2)) - 1 + 0,70 \hat{c}_w - 0,5U - 0,01$$

$$(5) \quad c_w = w_1 + w_2 + \dots + w_6$$

$$(6) \quad \hat{p}_w = b_1 \hat{p}_i(-2) + b_2 \hat{c}_w(-2)$$

onde  $\hat{p}_w$  é a taxa de variação do índice de reajuste salarial. Fica faltando uma ligação entre os  $w_j$  e  $\hat{p}_w$ , o que naturalmente difere em cada sistema de política salarial. Nossas simulações incorporam quatro possibilidades:

(a) Periodicidade Fixa - Neste caso a classe  $j$  recebe um reajuste salarial sempre que o número de meses decorridos desde seu último reajuste,  $m_j$ , atinge o número do período fixo do sistema, que indicamos por  $n$ . Então:

$$(7) \quad w_j = w_j(-1) \quad \text{se } m_j < n$$

$$w_j = w_j(-1) (p_w/p_w(-n)) \quad \text{se } m_j = n$$

Para simular uma redução do pico de salário real, basta fazer:

$$w_j = w_j(-1) (1 + r(p_w/p_w(-n) - 1)) \quad \text{se } m_j = n$$

onde  $r$  é a fração do aumento do índice de reajuste salarial que se permite repassar em aumentos salariais.

(b) Periodicidade Endógena - Neste caso deve ocorrer um reajuste automático sempre que o salário real médio acumulado desde o último reajuste atingir um determinado valor crítico  $v^c$ . Para implementar esta regra calcula-se o salário real médio acumulado desde o último reajuste,  $v_j$ , como se no período corrente não fosse ocorrer o reajuste automático:

$$(8) \quad v_j = (1/m_j) \sum_{k=0}^{k=m_j} (w_j(-k)/p_w(-k))$$

que deve ser comparado com o valor crítico  $v^c$  para detonar ou não um reajuste automático:

$$w_j = w_j(-1) \quad \text{se } v_j > v^c$$

$$w_j = w_j(-1) (1 + r(p_w/p_w(-m_j) - 1)) \quad \text{se } v_j \leq v^c$$

(c) Periodicidade Endógena com Período Mínimo - Este sistema só difere do anterior por impedir reajustes com períodos inferior a  $n$  meses. Para isto basta modificar a equação (9) de modo que o reajuste automático só ocorra se  $v_j \leq v^c$  e  $m_j \geq n$ .

(d) Periodicidade Decrescente - Este sistema opera do mesmo modo que o sistema de periodicidade fixa, mas com o período de reajuste aumentando a cada correção. Por exemplo, toda vez que houver um reajuste salarial, faz  $n = n + 1$ .

#### 4. Resultado de Simulação

Foram realizadas 10 simulações organizadas da seguinte forma:

- a) Periodicidade fixa com recomposição do pico - simulações 1 a 3.
- b) Periodicidade fixa com redução do pico - simulações 4 e 5.
- c) Periodicidade fixa com redução do pico e sincronização dos reajustes - simulações 6 e 7.
- d) Periodicidade endógena com redução do pico - simulação 8.
- e) Periodicidade decrescente - simulações 9 e 10.

Para interpretar os print-outs das simulações deve-se observar as seguintes convenções:

$$P3FT = \hat{p}_i$$

$$INPCT = \hat{p}_w(+2)$$

$$PICFT = \hat{p}_m$$

$$TCT = \hat{e}$$

VRMSJ, para J=1, ...6 = salário real médio verdadeiro acumulado nos últimos seis meses de cada classe de trabalhadores, definido como

$$\frac{1}{6} \sum_{k=0}^{k=6} (w_j(-k) / p_w(-k+2))$$

Este salário real médio é dito verdadeiro porque o salário real de cada mês é deflacionado pelo INPC do próprio mês, e não pelo INPC de dois meses atrás que é usado para os reajustes salariais.

VRM = média simples dos VRMSJ para J variando de 1 a 6,

KMJ, para  $j=1, \dots, 6$  = contador de meses decorridos desde o último reajuste. Esta variável assume valor zero sempre que não ocorre um reajuste salarial,

WRJ, para  $J=1 \dots 6$  = salário real verdadeiro a cada mês.

FARMJ, para  $J=1 \dots 6$  = salário real médio verdadeiro no último período de reajuste como fração do salário real médio verdadeiro no período anterior ao início da simulação.

Todas as simulações são feitas para sete anos, do primeiro mês do primeiro ano, mês 101, ao último mês do sétimo ano, mês 712. Em todos os casos, entretanto, nos primeiros seis meses, entre os meses 101 e 106, o modelo produz um equilíbrio inflacionário com inflação de 200% ao ano e reajustes semestrais de salários. Mudanças na política salarial só passam a ter efeito a partir do mês 107.

#### 4.1 - Simulação Básica: Equilíbrio Inflacionário com Periodicidade Fixa.

Esta é a simulação básica, que pode servir de ponto de referência nas análises das demais simulações. A política salarial recompõe o pico de salário real com periodicidade semestral, e como consequência, a economia mantém-se num equilíbrio inflacionário à taxa de 200% ao ano. A distribuição de renda permanece inalterada, com todos os salários reais médios semestrais iguais a 0,67. O salário real médio verdadeiro oscila de 0,833, no instante de um reajuste a 0,527, no mês imediatamente anterior a um reajuste, uma variação de 37%.

#### 4.2 - Choque Real com Periodicidade Fixa

Esta simulação permite-nos avaliar como o sistema de recomposição do pico com reajustes semestrais reage a uma mudança de preços relativos. Para isto foi introduzido um choque inflacionário autônomo de 30% na equação que determina o índice de correção salarial, entre os meses 107 e 206. É como se o INPC houvesse aumentado 30% permanentemente (em termos de nível) em relação ao INPC normal definido pela equação (6) anterior.

O resultado da simulação é uma aceleração da inflação para 277% no longo prazo, com uma queda do salário real médio semestral agregado (VRM) para 0,620, cerca de 7,5% menor que o nível inicial desta variável. Observe pelo comportamento dos VRMSJ que a distribuição de renda permanece inalterada a longo prazo.

#### 4.3 - Choque de Demanda com Periodicidade Fixa

Esta simulação representa um choque deflacionário de demanda. O hiato de produto na indústria de transformação, que está fixado em  $U = -0,02$  em todas as outras simulações, varia agora de um nível inicial de 0,25 em 101 até 0,305 em 112, declinando em seguida até anular-se em 401. A evolução mês a mês do hiato pode ser lida na coluna GAP do print-out.

A taxa de inflação cai para cerca de 130% ao ano no longo prazo, com um aumento de 10% no salário real médio semestral agregado (de .670 para .737). Não há repercussão distributiva significativa a longo prazo. (As pequenas diferenças que aparecem são erros de aproximação do simulador).

RID DATACENTRO

#### 4.4 - Periodicidade Fixa com Recomposição de 80% do Pico

Esta simulação supõe que a partir do mês 107 os reajustes semestrais recompõe apenas 80% do pico de salário real. Mais exatamente, a simulação dá a cada reajuste 80% do índice de correção salarial acumulado desde o último reajuste. Como se pode ver pela evolução dos salários reais verdadeiros, VRJ, a recomposição do pico é superior a 80% (da ordem de 95%) devido ao uso do INPC com defasagem de dois meses nos reajustes salariais.

A taxa de inflação dos preços industriais cai para cerca de 125% ao fim do primeiro ano da política (mês 206), para 66% ao fim do segundo ano (306), atingindo 20% ao fim do quarto ano. O salário real médio semestral agregado cai cerca de 4% no longo prazo, mas a incidência entre classes é diferenciada. A classe 6, a primeira a reajustar depois da introdução do redutor do pico, perde 6,6% de salário real médio no longo prazo, enquanto a classe 1, a última a entrar no regime de redução do pico, ganha 0,6% de salário real médio no longo prazo. Suge uma diferença da ordem de 8% entre os salários reais médios destas duas classes.

#### 4.5 - Periodicidade Fixa com Congelamento de Salários

Esta simulação é o caso extremo da recomposição parcial do pico, com a política salarial deixando de repassar qualquer inflação passada para salários a partir do mês 107.

O resultado é a quase total eliminação da inflação após o primeiro ano da política: a taxa de inflação em doze meses é apenas 7,6% em 206. A queda do salário real médio semestral agregado é comparável à que se observou na simulação anterior do redutor de 80%: para 0,647 neste caso contra 0,649 no caso do redutor de 80%. O impacto distributivo dentro da força de trabalho é, entretanto, mais acentuado. A classe 6 perde, no longo prazo, cerca de 25% de salário real médio, e a diferença entre os salários reais médios das classes 1 e 6 vai a quase 60%. A classe 1 tem um aumento de salário real médio de quase 20% no longo prazo.

#### 4.6 - Sincronização dos Reajustes

Esta simulação examina as consequências da sincronização de todos os reajustes salariais num sistema de recomposição semestral do pico. No mês 107 todas as seis classes de trabalhadores recebem uma correção salarial igual à inflação acumulada desde o último reajuste de cada uma, e a partir daí todos passam a ter a mesma data de reajuste, em intervalos semestrais.

A sincronização acelera bruscamente a inflação no mês em que ocorre, com os preços industriais crescendo 250% ao ano em 107, provocando de pois um declínio irregular ao longo do tempo até a nova taxa de equilíbrio de aproximadamente 140%. Nas datas de reajustes sincronizados, 107, 201, 207, etc., a taxa de inflação apresenta uma aceleração brusca, rompendo parcialmente a tendência de queda gradual ao longo do tempo.

O salário real médio semestral agregado cai cerca de 1% a longo prazo, mas é curioso observar a variação desordenada dos salários reais médios das seis classes no primeiro semestre posterior à sincronização. A partir de 201, entretanto, todos os salários reais médios voltam a igualar-se, e passam a evoluir identicamente no tempo, o que aliás é o que se pretende com a sincronização dos reajustes.

RID CATACENTRO  
 PERIODO ANTERIOR AO DIA 30 DE JANEIRO

#### 4.7 - Congelamento de Salários com Sincronização de Reajustes

Nesta simulação os reajustes salariais são sincronizados no mês 107, ocorrendo seis meses depois, em 201, o congelamento salarial. A inflação é praticamente eliminada até 301, com o salário real médio semestral agregado caindo cerca de 5% no longo prazo (para 0,641 em 305 com inflação nula). Observe, porém, que a política não tem repercussão distributiva no longo prazo. Entre 107 e 112 os salários reais médios das diversas classes tem um comportamento errático, mas a partir de 201 passa a ter o mesmo valor.

Table with 14 columns: 0973, 0974, 0975, 0976, 0977, 0978, 0979, 0980, 0981, 0982, 0983, 0984, 0985, 0986. Each column contains numerical values for 307 rows. The values are generally small decimals (e.g., .670, .675, .680) with some larger values (e.g., 2.000, 2.224, 1.944).

RIO DATACENTRO  
 SISTEMA DE CONTABILIDADE E GESTAO DE RECURSOS

RIO DATACENTRO  
 SISTEMA DE CONTABILIDADE E GESTAO DE RECURSOS

#### 4.8 - Periodicidade Endógena com Recomposição de 80% do Pico

Esta simulação é semelhante à simulação 4 anterior ao supor que a partir de 107 cada reajuste salarial incorpora apenas 80% da variação passada do índice de correção salarial mas aqui o período de reajuste varia endogenamente de modo a manter um valor crítico mínimo do salário real médio acumulado entre reajustes, como na equação (9) anterior.

Os resultados de simulação mostram, entretanto, que o sistema não consegue defender efetivamente os salários reais médios dos trabalhadores que caem no agregado cerca de 4% a longo prazo. Curiosamente, a queda de salário real é maior aqui, na altura de 712, do que na simulação 4 anterior, que supõe redução de 80% no pico e periodicidade fixa. O impacto distributivo entre trabalhadores das duas políticas parecem igualmente severos.

Há duas razões para o insucesso desta política salarial em cumprir o papel para o qual foi supostamente concebida de defender os salários reais médios ao longo do tempo. Em primeiro lugar, o fato de que o sistema opera com base em valores reais médios calculados com o INPC defasado em dois meses (o que é uma limitação de ordem prática), introduz uma margem de erro nos valores reais médios verdadeiros quando a taxa de inflação varia. Mais importante, porém, é o fato de os períodos de reajuste tenderem a reduzir-se ao longo do tempo, levando o sistema a operar com reajustes de periodicidade fixa a partir de certo momento. Nesta simulação a classe 6 passa a ter reajustes mensais, que é

o período mínimo aceito pelo programa de simulação, a partir de 202. Do mês 208 em diante, todas as classes tem reajustes mensais.

Em termos de redução da inflação o resultado é menos favorável aqui que no caso da redução do pico com periodicidade fixa. Ao fim do primeiro ano da política, em 206, a inflação dos preços industriais caiu apenas para 180%, enquanto que com periodicidade fixa teria caído para 125%. Em 306 a taxa de inflação é de 90% na presente simulação, contra 65% com periodicidade fixa. Somente por volta do quarto ano, em que o sistema aqui simulado já está operando por algum tempo com reajustes mensais, é que a desaceleração inflacionária torna-se mais rápida que no caso dos reajustes semestrais da simulação 4.

FORMOSA EXPERIMENTAL CATCHER NO 10 DE JAVIERO

FORMOSA EXPERIMENTAL CATCHER NO 10 DE JAVIERO

#### 4.9 - Periodicidade Decrescente

Esta simulação representa um sistema em que o período de reajuste vai se tornando progressivamente maior ao longo do tempo. A partir de 107, cada classe tem o primeiro reajuste seis meses depois do último reajuste, o segundo reajuste sete meses depois do último reajuste, o terceiro oito meses depois, e assim por diante, até que a inflação desapareça. No presente caso, o período de reajuste chega a treze meses no final do sétimo ano.

O sistema introduz uma tendência declinante na inflação, mas com um comportamento nitidamente cíclico. Ao final do sétimo ano, a taxa de inflação está oscilando entre 65% e 80%. Os salários reais médios, tanto por classe como o agregado, também têm comportamentos cíclicos, mas sem qualquer tendência nítida.

RIO DATACENTRO  
 PORTAL GENERAL DE CÁMARA DE COMERCIO DE JAMBO

#### 4.10 - Periodicidade Decrescente com Sincronização

Esta simulação só difere da anterior na hipótese de que os reajustes são sincronizados em 107. A partir deste reajuste de sincronização, o período vai aumentando de seis, para sete, para oito, até atingir treze meses em 711.

Os resultados para inflação e salários reais médios continuam a ter um forte componente cíclico, mas neste caso as tendências aparecem mais nitidamente: queda da inflação e redução dos salários reais médios. A impressão que se tem, entretanto, é que este sistema produz muita perda salarial por ponto de desaceleração inflacionária. Em comparação, por exemplo, com o sistema de congelamento de salários e sincronização de reajustes da simulação 7, este sistema obtém o mesmo valor de salário real médio semestral 0,638 em 712 para 46% de inflação aqui contra estabilidade plena de preços no outro caso.
