**Zusammenfassung***Importkonkurrenz aus Niedriglohnländern und populistische Gegenreaktion: Der Fall Italiens*

Dieses Papier untersucht empirisch die Bedeutung der Handelsglobalisierung für die Entwicklung populistischer Tendenzen. Wir betrachten den schnell zunehmenden Importwettbewerb aus China stellvertretend für den Handelsschock und vergleichen das Abstimmungsverhalten bei den Parlamentswahlen von 1992 bis 2013 in rund 8,000 italienischen Gemeinden, die dem Handelsschock unterschiedlich stark ausgesetzt sind. Wir nutzen chinesische Exportströme in andere Länder mit hohem Einkommen als Instrumentvariable für Importe aus China nach Italien und schätzen ein First-Differences-Modell. Unsere Ergebnisse zeigen, dass die Handelsglobalisierung die Zustimmung bei der Wahl populistischer Parteien begünstigt und darüber hinaus die Tendenz fördert, ungültige Stimmen abzugeben oder sich sogar der Stimme zu enthalten. Um diese Ergebnisse zu erklären, liefern wir Belege dafür, dass der Importwettbewerb die Arbeitsbedingungen verschlechtert - höhere Arbeitslosigkeit, geringeres Einkommen und weniger Ausgaben für langlebigen Konsum - und das Einkommensgefälle verschärft. Schließlich weisen wir darauf hin, dass vermehrte öffentliche Ausgaben eine Rolle bei der Milderung der politischen Folgen des Handelsschocks spielen, wohl weil sie die wirtschaftliche Misere der Wähler lindern.

**Abstract***Low-wage import competition and populist backlash: The case of Italy*

This paper empirically studies the role of trade globalization in shifting the electoral base towards populism. We proxy trade shock with swiftly rising import competition from China and compare the voting pattern at the parliamentary national elections from 1992 to 2013 in about 8,000 Italian municipalities differently exposed to the trade shock. We instrument import competition with Chinese export flows to other high-income countries and estimate the model in first differences. Our results indicate that trade globalization increases support for populist parties, besides fostering a tendency to cast invalid votes or even abstain from voting. To rationalize these findings, we offer evidence that import competition worsens labor market conditions – higher unemployment, lower income and durable consumption – and increases inequality. Finally, we point out that public expenditure plays a role in mitigating the political consequences of the trade shock, arguably because it alleviates economic distress.

**Keywords:** trade globalization, populism, inequality

## 1. Introduction

In many developed Western societies, populism is on the rise at an alarming pace. The outcome of the Brexit referendum and the election of Donald Trump in the US are the most eye-catching examples of this phenomenon, but several other countries are witnessing similar tendencies: in Italy, France, Germany, the Netherlands, Austria, and the Czech Republic, populist parties recently achieved large electoral support at general polls. The growing concern about their success has given rise to a widespread debate on the causes of the populist backlash in the Western World, as well as on potential remedies.

Trade globalization is one of the key candidate economic determinants, the channels at work being labor market adjustments. Autor et al. (2013) outline a simple theoretical trade model based on monopolistic competition and heterogeneity in industry labor productivity across countries, according to which positive shocks to low-wage countries' export supply can cause employment in the traded-good sectors of developed countries to contract on net as long as trade is not balanced. This mechanism captures the widely held perception of the redistributive effect of trade globalization *between* countries, with developed economies being the losers and low-wage developing exporters the winners (the "Great Convergence", Baldwin et al. 2016). On the other hand, theory also posits redistributive effects *within* (developed) countries (the parallel "Great Divergence", Moretti 2012), as Rodrik (2018) recently pointed out.<sup>1</sup>

The present paper contributes to this debate along three lines. First, we add new empirical evidence on the role of trade globalization in moving the equilibrium of the political game towards populism. Specifically, we compare voting patterns at the Italian national parliamentary elections over the 1992-2013 period (starting from the trade globalization take-off) in about 8,000 municipalities differently exposed to the trade shock. The model is estimated in first differences so as to control for municipality-level time-invariant idiosyncratic shocks, while a full set of time fixed effects accounts for country-level time-varying perturbations. Following the literature pioneered by Autor et al. (2013, 2016), Chinese import competition proxies for trade globalization. The populist vote is computed by relying on the classification of populist parties provided in Inglehart and Norris (2016). Next, we explore economic fundamentals behind the voting reaction by testing whether the "China syndrome" manifests itself also in terms of employment, income, durable consumption (proxied by new car sales), and inequality. Finally, we complete the picture by examining if Keynesian-type policy intervention, which should at least in part mitigate the short-term economic costs of globalization,

---

<sup>1</sup> Rodrik (2018) refers to the theorem in Stolper and Samuelson (1941), which entails very neat distributional implications from opening up to trade. Assuming a two-good and two-factor model of production, with no frictions in the inter-sectoral mobility of inputs, trade liberalization makes the factor that is used intensively in the importable good worse off, by inducing a decline in its payment. If the two factors are skilled and unskilled labor, the prediction for rich countries would be that trade increases the return to skilled labor and lowers the return to unskilled labor, so raising income inequality. Beyond theoretical arguments, Rodrik (2018) suggests also that the populist backlash comes as no surprise in light of economic history: the first era of globalization started in the second half of the nineteenth century, led to the emergence of history's first self-conscious populist movement in the US rallying against the Gold Standard and ended in the first half of the twentieth century with the spread of Communism, Fascism and Nazism. See Harrison et al. (2011) for a survey on the effects of trade on inequality.

exerts a counteracting effect on populism. Absent official figures on public expenditure at the municipality level, we resort to two proxy variables. The first is defined as the interaction between the nationwide public expenditure figure and a measure of local specialization in government consumption. The second is simply the expenditure of municipal governments.

The identification of the causal effect of trade shock on voting behavior requires dealing with the potential endogeneity of import exposure, which may arise from various sources. For example, there might be omitted municipality-time level unobserved shocks (e.g. a sectoral, asymmetric, negative shock to local manufacturing industries) that attract imports from China and, at the same time, induce a populist reaction among voters; its omission would bias the OLS parameter upwards. Moreover, the populist vote may result in protectionist trade policies that reduce import flows: in this case, reverse causality would lead to a downward bias of the OLS estimate. Last but not least, we cannot rule out some measurement error. To address the possible endogeneity threat, we instrument Italian imports from China with Chinese exports to a set of non-euro high-income countries that account for a small share of Italy's total trade. The instrument is intended to capture only the push factor underlying Chinese export performance; at the same time, it involves economies weakly connected to Italy in terms of trade, so minimizing the risk of invalidating the exclusion restriction assumption.

Endogeneity is likely to be an issue also with respect to municipal governments' expenditure, for example because of reverse causation problems. We tackle this concern by instrumenting municipal governments' expenditure with the Internal Stability Pact, a set of fiscal rules providing stricter fiscal discipline that the central government imposed in some years only on larger municipalities.

Our results indicate that exposure to Chinese import competition strengthens support for populist parties: according to the IV preferred specification, a one standard deviation increase in the annual change of imports from China (about 145 dollars per worker at 2000 prices) entails a rise in the annual change of the populist vote share equal to 0.4 percentage points, about one third of the average value of the dependent variable and one tenth of its standard deviation. The magnitude of the impact is non-negligible, especially if one takes into account that the vote response regards *all* voters and not just those working in the tradable sectors. This result is robust to a number of sensitivity checks, pertaining, among others, to the measurement of the trade shock, the classification of populist parties, the potential confounding role of immigration and the introduction of the euro. Moreover, we find that voters' protest reaction also takes the form of an increase in invalid (blank and null) ballot papers and a drop in voter turnout. To rationalize our results, we show that Chinese import penetration negatively affects employment, income and consumption, so signaling that globalization has a redistributive role *between* countries. We also detect a positive effect on income inequality, hinting at the emergence of winners and losers from globalization also *within* the country under scrutiny. Finally, we provide some evidence that public expenditure partially offsets the China shock, which suggests that, at least in the short term, social protection policies are likely to be an effective tool for mitigating the negative consequences of low-wage import competition.

Our paper is mainly related to the empirical literature on the political consequences of globalization. Within this literature, Autor et al. (2016) is the seminal paper looking at the role of rising exports from China on political polarization: the Chinese import shock affects the ideological composition of the US Congress, with politicians moving towards the very left or the very right of the political spectrum. Subsequent contributions essentially adopt the same methodology to estimate the China effect in different countries and share the result that low-wage import competition increases voting for far-right parties.<sup>2</sup> As for the redistributive effects of trade shocks, we refer to the set of studies that, in the wake of Autor et al. (2013), assess local labor market adjustment costs, both in terms of job displacements and reduced earnings (Dauth et al., 2014; Malgouyres, 2017a). Our analysis of the compensatory function of public expenditure speaks, instead, to the literature on the political consequences of fiscal austerity: Fetzner (forthcoming) shows that fiscal austerity correlated with support for the UK Independence Party, first, and with the victory of the Leave campaign, then.

An important but less related research agenda is that shedding light on the determinants of populism. While some scholars propose a cultural backlash hypothesis to explain today's success of populist parties in the Western World (e.g. Ingelhart and Norris, 2016), others trace it back to economic insecurity (Dal Bò et al., 2018), resulting especially from globalization (e.g. Guiso et al. 2017; Rodrik, 2018) and the 2008-2013 financial crisis (e.g. Guiso et al., 2019; Algan et al., 2017; Dustman et al., 2017).

We depart from the existing literature in many respects. The most important novelty relates to the role of government intervention in counteracting the pressures of trade globalization. While the labor market and political impact of the "China syndrome" is somehow well-established, no study explicitly addresses its policy implications. Our paper is the first to show that Keynesian-type interventions can help mitigate voters' reaction at the polls. Unlike Fetzner (forthcoming), we find that this result holds for general elections spanning over more than a decade, rather than just for a one-off and unique event such as the Brexit referendum.

Even within the realm of estimating China's electoral effect in developed countries, our paper adds to the established knowledge. First, as Caselli et al. (2019), we consider the Italian case, which – we argue – is particularly interesting. Indeed, Italy displays by far one of the highest vote shares for populist parties among large rich countries (Figure 1). Moreover, ahead of the trade shock, the Italian product specialization model was more heavily centered on the less technologically advanced sectors (e.g., textile, apparel, leather, footwear, furniture) compared to its Western competitors, so making the country more vulnerable to the China shock. Figure 2 illustrates that in 1992 the Italian economy spent a largely smaller share of its GDP on research and development than other highly industrialized countries and that the Italian loss in worldwide export market shares over the 1992-2013 period was larger than the average. Last but not least, Italy is one of the Western developed

---

<sup>2</sup> Dippel et al. (2017) study German NUTS 3 regions from 1987 to 2009; Malgouyres (2017b) focuses on small French communities from 1995 to 2012; Caselli et al. (2019) use Italian labor market areas (over 600 units) as main unit of analysis from 1994 to 2008; Colantone and Stanig (2018) combine district-level voting data and European NUTS 2 region-level trade data between 1988 and 2007, Branstetter et al. (2019) conduct their analysis for Portugal at the firm-level.

countries that more urgently needs structural, but often unpopular, reforms to spur growth (IMF, 2017; OECD, 2017); populist parties make their implementation more difficult, even when they are not in power (Guiso et al., 2017).

Second, and differently from Caselli et al. (2019), we enrich the analysis by exploring mechanisms behind the causal effect of globalization on populism. We focus on labor market adjustments, and show that the increase in *within*-country income inequality goes hand in hand with the distributional frictions *between*-countries. In addition, we are the first to point out that the China effect extends also to durable consumption, proxied by new car sales.

Further minor contributions include the focus on populism – rather than on extreme right parties – as a more general form of protest vote<sup>3</sup>, the consideration of invalid ballot papers and voter turnout as additional political outcomes, the robustness of our core findings on populism to immigration and the introduction of the euro, the inclusion of former Communist countries to the pool of new trade competitors, slight improvements in the construction of the instrument for import exposure.

The rest of the paper is organized as follows. The next Section discusses data and measurement issues, while Section 3 describes our empirical strategy. In Section 4, we present our core findings on the effect of trade shock on populism (and other forms of protest vote). Section 5 is devoted to the results for potential underlying transmission channels. In Section 6, we consider the role of public expenditure, and Section 7 concludes.

## 2. Data and measurement issues

**Measuring exposure to import competition.** To measure the exposure of Italian municipalities to import competition from China, we use the index developed by Autor et al. (2013), which maps sector-specific national import shocks to local units on the basis of their initial industry specialization:

$$\Delta IC_{it} = \sum_k \frac{L_{ikt_0}}{L_{it_0}} \frac{\Delta M_{kt}^{ITA}}{L_{kt_0}} \quad (1)$$

where  $i$  indicates municipalities;  $t$  denotes election years (1994, 1996, 2001, 2006, 2008, 2013);  $k$  indicates tradeable sectors;  $\Delta M_{kt}^{ITA}$  is the yearly average change in imports (in real terms) from China to Italy observed in sector  $k$  over the length of a legislature;  $L_{kt_0}$  is Italian employment in sector  $k$  measured on the basis of Census data at the start of the decade (1991 for the periods 1992-1994, 1994-1996, 1996-2001; 2001 for the periods 2001-2006, 2006-2008, 2008-2013);  $L_{ikt_0}$  is the start-of-decade employment in municipality  $i$  and sector  $k$ ; and  $L_{it_0}$  is the start-of-decade total employment in municipality  $i$ .

---

<sup>3</sup> It is increasingly recognized that certain core features of populist parties are not necessarily prototypical of a radical right party. From an empirical point of view, in our sample the Five Star Movement (labelled as populist by all the prevailing classifications) cannot be placed along the usual right-left dimension of the political spectrum (Bordignon and Ceccherini, 2015).

Data on imports are taken from the Observatory of Economic Complexity at the MIT Media Lab, which combines historical Feenstra's data (1962-2000) from the Center for International Trade Data with more recent data (2001-2014) of UN COMTRADE. We have access to annual bilateral trade flows for 262 countries and 989 different products for the four-digit SITC revision 2 classification over the timespan 1962-2014. Employment at the municipality-sector level is drawn from the Italian Statistical Agency (Istat) for the Census years 1991, 2001 and 2011. Up to 2001 the number of workers in local units of enterprises is based on the two-digit NACE revision 1 breakdown, while for 2011 it is available according to the two-digit NACE revision 2 classification. NACE revision 2 codes have been converted to NACE revision 1 codes using a conversion matrix developed by Perani and Cirillo (2015). The administrative boundaries of Italian municipalities are those used in the Istat 2011 general Census, after controlling for municipality mergers. In order to match trade data with employment data, SITC revision 2 commodities must be matched with NACE revision 1 industrial categories. We use the correspondence table between SITC revision 2 and ISIC revision 3 (equivalent to NACE revision 1 up to two digits) provided by Affendy et al. (2010). Trade values of not-uniquely-mapped goods are assigned to two-digit NACE revision 1 sectors using, firstly, the UN conversion table between SITC revision 2 and SITC revision 3 in combination with the WITS concordance table between SITC revision 3 and NACE revision 1, and then, eventually, national employment shares at the start of each decade (reflecting the initial importance of each sector in the economy). At the end, we are left with international trade data for 34 two-digit NACE revision 1 industries, almost all of them concerning non-service activities (see Table A1). Trade flows for Italy have been deflated by applying the Italian implicit gross value added deflator, taken from the OECD STAN database.

Figure 3a shows that Chinese exports took off at the beginning of the nineties. Since then, they have been growing at a much faster pace with respect to worldwide exports, and Italy has not been immune to such an impetuous trend. In Figure 3b, we display the sectoral contribution to the total growth rate of imports from China in real terms over the period under examination. Between 1992 and 2013, Italian imports from China grew eight-fold, so that by 2013 China became Italy's third largest import origin after Germany and France; the compounded average growth rate exceeded 10 per cent. The main contributions came from machineries (NACE revision 1 codes 29 and 30), textiles and wearing apparel (17, 18), electrical machinery and communication equipment (31, 32), chemical products (24) and leather and footwear (19).

**Identifying populist parties.** Data on election outcomes come from the Ministry of Interior and are available at the municipality level (about 8,000 municipalities).<sup>4</sup> We sourced information on the votes for each party, the invalid ballot papers, and the turnout at the polling booths for the general parliamentary elections that took place in 1992, 1994, 1996, 2001, 2006, 2008, and 2013. In light of the broader political involvement envisaged by the regulation of the Chamber of Deputies, our focus is specifically on the elections for the lower house of the legislature.<sup>5</sup> Over the years under scrutiny,

---

<sup>4</sup> <http://elezionistorico.interno.it/>. Data at our disposal do not include the small autonomous Aosta Valley region (0.2 per cent of the Italian population).

<sup>5</sup> The Italian parliament is composed of two houses: the Chamber of Deputies and the Senate of the Republic. According to the principle of perfect bicameralism, the two houses perform identical functions. The only

electoral rules changed, with a different mix of parliamentary seats assigned by majoritarian rule or by proportional rule. In all elections, we restrict our attention to votes under the proportional rule, which is more apt to mirror political preferences.

With voting data in hand, we identify populist parties by relying on the classification provided in Inglehart and Norris (2016), who take Mudde's (2007) very influential contribution as a basis. Mudde (2007) suggests that populism presents three recurring features: (i) anti-establishment ideology that considers society to be ultimately separated into two homogenous and antagonistic groups – the 'pure people' and the 'corrupt elite' – and argues that politics should be an expression of the will of the people; (ii) authoritarianism belief in a strictly ordered society in which infringements of authority are to be punished severely; and (iii) nativism, holding that states should be inhabited exclusively by members of the native group ("the nation"), and non-native elements – whether persons or ideas – are fundamentally threats to the homogenous nation-state. Inglehart and Norris (2016) bring this definition to the data by exploiting the 2014 Chapel Hill Expert Survey (CHES) in which 337 political scientists are asked to rate the positioning of 268 parties (those with seats in Parliament) in 31 European countries on a number of different policy issues. Experts' answers to 13 selected questions<sup>6</sup> are mapped, by means of factor analysis, into scores and a party is labelled as populist if the standardized sum of its scores related to cultural aspects is above a given threshold. Italian parties coded as populist, on the occasion of the 2013 elections, are the Northern League (*Lega Nord*), the Five Star Movement (*Movimento Cinque Stelle*) and the Brothers of Italy (*Fratelli d'Italia*). In relation to our aim, this approach has two limitations: it does not span the full spectrum of Italian political forces (those that did not win any seat in Parliament) and, more importantly, it does not take into account political forces involved in the elections before 2013. Hence, we properly integrate Inglehart and Norris' (2016) list by tracing parties back in time so that it ultimately includes the Northern League (Lombard League in 1992), the National Alliance (*Alleanza Nazionale*), the Italian Social Movement (*Movimento Sociale Italiano*), the Tricolor Flame (*Fiamma Tricolore*), the Right-Tricolor Flame (*La Destra-Fiamma Tricolore*), Brothers of Italy (*Fratelli d'Italia*), and the Five Star Movement (*Movimento Cinque Stelle*). Table A2 in the Appendix reports the year-by-year list of populist parties considered in this paper.

In addition to the classification of Inglehart and Norris (2016), there is also the one proposed by Van Kessel (2015) and adopted by Guiso et al. (2017). The main advantage of the latter is that it is time-variant. However, unlike Inglehart and Norris (2016), van Kessel (2015) captures only one of the three features of populism (the anti-elite rhetoric) that Mudde (2007) highlights. On the other hand, the static character of Inglehart and Norris' (2016) classification is not very relevant in our case as

---

differences between them lie in the membership and the rules for the election of their members. The Chamber of Deputies has 630 members, who must be at least 25 years old and are elected by all Italian citizens over the age of 18. The Senate has 315 members, who must be at least 40 years old and are elected by all Italian citizens over the age of 25. In addition to elected members, the Senate also includes life senators, who are appointed by the President of the Republic.

<sup>6</sup> They concern the following dimensions: support for traditional values, liberal social lifestyles, nationalism, tough law and order, multiculturalism, immigration, rights for ethnic minorities, religious principles in politics, rural interests, wealth redistribution, as well as stance towards market deregulation, state management of the economy, and preferences for either tax cuts or public services.

we focus only on a single country and, therefore, recovering the time dimension of the data is straightforward.<sup>7</sup> The main difference between the two classifications is that van Kessel (2015) labels as populist the parties headed by Berlusconi (*Forza Italia* and the People of Freedom – *Popolo della libertà*), but not all post-fascist parties (the National Alliance, the Italian Social Movement, the Tricolor Flame, the Right-Tricolor Flame, Brothers of Italy). Anyway, we show that our results still hold either when we adopt the list of van Kessel (2015) or when we enlarge our set to include all parties in the coalitions led by Berlusconi.

Figure 4 shows the overall increasing populist vote trend in Italian general elections. In 1992 the populist share was about 15 per cent; in the next two elections it rose, exceeding 25 percent four years later; after that, the populist share went monotonically down (except for the 2006 election), dipping to slightly below 15 percent in 2008. Finally, in the 2013 election, the populist parties nearly tripled their share. The figure also displays large variability in populism across municipalities.

**Proxies for immigration and euro.** Immigration is simply defined as the average annual change of the share of foreigners over native population:

$$\Delta\left(\frac{Immigrants_{it}}{Natives_{it}}\right).$$

Data at the municipality-year level come from Istat and are available only from 2001 onwards.

Exposure to the euro is given by:

$$\sum_k \frac{L_{ikt_0}}{L_{it_0}} (1 - \vartheta_k) \Delta REER_t$$

where  $\Delta REER_t$  is the average annual growth rate of Italy's real effective exchange rate over a parliamentary term (a positive value indicates appreciation and, so, loss of competitiveness). Data on  $\Delta REER_t$  are taken from the Bank of International Settlements. To map the country-level exchange rate shock to sectors, we assume that activities with low human capital content are more sensitive to price competition, in accordance with Bugamelli et al. (2010). Specifically,  $\vartheta_k$  is the skill intensity in manufacturing sector  $k$  as reported by the same authors. Local exposure is then retrieved, in parallel with equation (1), by taking a weighted summation of the industry-level changes, where the weights reflect the start-of-decade relative importance of each sector in a given municipality.<sup>8</sup>

**Income, inequality and consumption.** Confidential data on average income levels at the municipality level are made available by the Ministry of Economy and Finance for the years from

<sup>7</sup> As far as Italy is concerned, the classification in Rodrik (2018) coincides with that of van Kessel (2015).

<sup>8</sup> The summation is over manufacturing sectors, the only ones for which the skill intensity index is available (see Table A1).

2003 to 2014.<sup>9</sup> As figures are based on tax records, we proceed to adjust them for tax evasion as follows. Comparing survey results with official tax records, Marino and Zizza (2008) derive a tax evasion rate by gender, age, geographical area, job type (employee, self-employed, etc.). We map these rates into municipalities according to their composition in terms of the same variables as per 2001 Census and divide, then, original income levels by  $1 - (\text{imputed tax evasion rate})$ . The dataset provided by the Ministry of Economy and Finance also includes information on inequality, as measured by the Gini index. Data on new car sales, on the other hand, are drawn from the Italian Ministry of Infrastructure and Transport over the period 2001-2013.<sup>10</sup>

**Public expenditure.** Unfortunately, official figures on public spending at the municipality-year level do not exist. The most granular level is the region-year one: aggregating about 8,000 municipalities into 20 regions would be very unsatisfying. We adopt two second-best alternative measures.

From the Input-Output accounts it becomes evident that the importance of government as a final consumer varies widely across sectors. For example, government purchases are zero for “private households with employed person” (NACE revision 1 code 40, 5<sup>th</sup> percentile), while they amount to 72 per cent of total use for “Health and social work” (NACE revision Code 1 85, 95<sup>th</sup> percentile). At the same time, sectoral distribution turns out to be very different across municipalities. In light of such observations, a first proxy for exposure to public expenditure at the municipality-year level can be computed as:

$$\sum_k \frac{L_{ikt_0}}{L_{it_0}} \rho_k \frac{\Delta \text{NatExp}_t}{N_{t_0}}.$$

where  $\Delta \text{NatExp}_t$  is the yearly average change in nationwide public expenditure taken from Istat and available from 1996 onwards. This country-level fiscal shock - normalized by the Italian population at the start of the decade (1991 for the period 1996-2001; 2001 for the periods 2001-2006, 2006-2008, 2008-2013),  $N_{t_0}$  - is apportioned to industries according to their dependence on public spending. Specifically,  $\rho_k$  is the share of the final demand for goods from sector  $k$  incurred by the public administration (as it results from the 1995 Input-Output accounts released by Istat, see Table A1). Municipality-level vulnerability is derived again, in parallel with equation (1), by exploiting the local heterogeneity in the employment industry mix. This proxy takes into account the entire spectrum of public expenditure and can be considered exogenous with respect to populism at the municipality-year level; on the other hand, it might be affected by some measurement error if technology - approximated by  $\rho_k$  - differs across municipalities. We also use a variant of the above expression, where expenditure is restricted to welfare-related objectives (health, education and social protection, defined according the Classification Of Function Of Government – COFOG); in this case, the summation ranges only over the corresponding sectors (NACE revision 1 codes 75, 80, 85 and 92).

---

<sup>9</sup> Unfortunately, available data refer to average income and not to wages. Assuming that the impact of import competition on sources of income other than wages (e.g. rents, capital gains, etc.) is lower, our findings are to be considered as a lower bound for the effect on wages.

<sup>10</sup> <http://dati.mit.gov.it/catalog/dataset/parco-circolante-dei-veicoli>.

The second proxy for exposure to local public expenditure is given by the average annual change in per capita current spending of the municipal government. Municipal governments' current expenditure is taken from the Ministry of the Interior (certificates of the balance sheet account – *Certificati di conto consuntivo*) and is available only for the 2000s. Municipal population is that of the 2001 Census. The main advantage of this proxy is that there is no error in imputing money to territories, but it comes with a very partial coverage of the overall public service provision in a municipality (less than 10%).

### 3. Empirical strategy

To assess the causal effect of import competition on the populist vote, we adopt the following specification:

$$\Delta Y_{it} = \beta \Delta IC_{it} + X'_{it_0} \gamma + \delta_t + \gamma_{r(i)} + \varepsilon_{it}. \quad (2)$$

As above,  $i$  indicates municipalities,  $t$  denotes the election years (1994, 1996, 2001, 2006, 2008, 2013) and  $t_0$  refers to the Census years 1991 (for the periods 1992-1994, 1994-1996, 1996-2001) and 2001 (for the periods 2001-2006, 2006-2008, 2008-2013).  $\Delta Y_{it}$  is the average annual change of the populist vote share between two subsequent elections;  $\Delta IC_{it}$  is the trade shock defined in (1);  $\delta_t$  are period fixed effects and  $\gamma_{r(i)}$  are region-level fixed effects ( $r = \text{North, Centre, South}$ );  $X_{it_0}$  includes a set of (time-variant and invariant) variables – all measured at  $t_0$  – aimed at controlling for economic, demographic, social, and geographic differences across municipalities: share of workers employed in manufacturing sectors, population density, share of female working-age population, share of the population that holds at least a high-school diploma, aging index, a dummy capturing whether the territory is coastal or not, and a measure of terrain roughness. Data for all these covariates are taken from Istat.  $\varepsilon_{it}$  is an idiosyncratic shock.<sup>11</sup> Table 1 shows the main descriptive statistics.

Estimating a first difference model allows us to control for municipality-level time-invariant heterogeneity. However, endogeneity might arise primarily from omitted municipality-period idiosyncratic shocks. For example, suppose that a negative sectoral shock hits the domestic economy: if the spatial distribution of the affected industry is not uniform (as is often the case), the shock may disproportionately worsen the labor market of the municipalities specialized in that industry, so generating a populist reaction at the polls; at the same time, the negative sectoral shock may attract imports from China. In such a case, the OLS estimate for  $\beta$  would be biased upwards. On the other hand, reverse causality may generate downward bias if populism gives rise to protectionist trade measures, and measurement error might be at work as well.

To address the potential endogeneity threat, we follow the approach in Autor et al. (2013) and instrument  $\Delta IC_{it}$  with:

---

<sup>11</sup> Like the literature in the field, we cannot distinguish demand and supply effect (Guiso et al. 2017): our results are about the effect of the import competition shock on the political market equilibrium.

$$Z_{it} = \sum_k \frac{L_{ikt_0}}{L_{it_0}} \frac{\Delta M_{kt}^{OTHER}}{L_{kt_0}}. \quad (3)$$

Equation (3) is analogous to equation (1) except for  $\Delta M_{kt}^{OTHER}$ , which is the yearly average change (over a legislature) in real import flows of industry- $k$  goods from China to a set of non-euro OECD countries that, between 1992 and 2013, exhibited high growth rates of trade with China, but accounted for an average share in total Italian trade of less than 1 per cent: Norway, Denmark, Australia, Canada, Iceland and New Zealand.<sup>12</sup> The idea underlying  $Z_{it}$  is that it captures only supply-side improvements in Chinese export competitiveness (due, for example, to productivity growth); at the same time, we assume that  $Z_{it}$  affects the populist vote only through its effect on  $\Delta IC_{it}$ . The latter assumption might be invalidated were we to take advanced economies with strong trade connections to Italy as alternative destination areas. To minimize this risk, we select high-income countries that are weakly integrated (in trade terms) with Italy.

To study the role of public intervention, we enrich equation (2) with a proxy for local public spending. Endogeneity issues can arise when the proxy is given by expenditure of the municipal government: the latter may well react to local populism. To control for this, we instrument our regressor with the Internal Stability Pact (ISP). This set of rules reflects at the sub-national level the Stability and Growth Pact adopted by Italy in 1997. The ISP was introduced in 1999 and required municipal governments to keep their fiscal balance under tight control (Grembi et al., 2016). Initially, the ISP regarded all municipalities; after 2001, an exemption was granted to municipalities with less than 5,000 inhabitants, probably because of the recognition of economies of scale in managing the municipal government. The threshold was further lowered to 1,000 inhabitants in 2013 (see Table A3). The instrument is built as the average  $ISP_{it}$  over the legislature ending in year  $t$  for municipalities  $i$  of regions with ordinary status.

#### 4. Results on populism

**Baseline findings.** Table 2 shows the baseline estimates. In column (1), we start by displaying the OLS results of a very parsimonious specification including only import competition and period fixed effects. Estimates suggest a positive (and highly statistically significant) correlation between the change in the trade shock and the change in the populist vote share. In the next two columns, we enrich the specification by including area fixed effects  $\gamma_{r(i)}$  and other controls  $X_{it_0}$ : the point estimate of the coefficient of interest and its precision are very stable. Columns (4)-(6) document the results derived using the IV estimator. The instrument is always highly significant in predicting the potentially endogenous variable. The impact of the trade shock on the share of preferences for populist parties is highly significant, though slightly smaller in size than its OLS counterpart. The downward revision of the point estimates suggests that the potential omitted variable bias stemming from a negative sectoral supply shock dominates the potential downward bias related to reverse causality and/or measurement error. In our preferred specification in column (6), which includes area fixed effects and controls, the estimate for the coefficient of interest is 0.0249 and is

---

<sup>12</sup> Trade flows of each of these countries have been deflated by applying the respective implicit gross value added deflator, taken either from the OECD STAN database (if available) or from the EU KLEMS database.

very precisely measured. To put this into perspective, a one standard deviation increase in the yearly average change of Chinese imports (about 145 dollars per worker at 2000 prices) entails a rise in the average annual change of the populist vote share equal to one third of the average value of the dependent variable and one tenth of its standard deviation. The impact is surprisingly large, especially if one considers that the vote response regards *all* voters, and not just those working in the tradeable sectors (about 45 per cent of total workers) who are directly affected by rising trade exposure.

**Robustness checks.** In Table 3, we carry out a number of robustness checks for our preferred specification (Table 2, column 6). A first set of robustness checks deals with the challenge of properly identifying populist parties. As outlined in Section 2, van Kessel (2015) proposes an alternative list of Italian populist parties, which excludes Brothers of Italy (and, implicitly, its forerunner parties such as the Italian Social Movement, etc.), but includes Berlusconi's political forces *Forza Italia* and *Popolo della Libertà* (that is, *Forza Italia* fused with National Alliance). When we rely on this classification – which we enrich by including all minor parties in the coalitions led by Berlusconi – results are confirmed (column 1). We also check for the robustness of our classification to the inclusion of Berlusconi's and his allies' parties and, again, the test is reassuring (column 2). So far we computed the populist vote share by including in the denominator valid votes for all parties. Yet, the currently available classifications of populist political forces do not scrutinize minor parties (those with no seats in Parliament; see Section 2). In column 3, we divide the number of populist votes - as per Inglehart and Norris (2016) - only by the valid votes for parties with parliamentary representation and the coefficient of interest is again very stable.

The next four columns address measurement issues that pertain to the key independent variable. We chose import competition from China as our preferred measure of trade shock for the sake of comparability with the literature in the field. However, one might reasonably argue that China is not the only big player in trade globalization. Among Italy's top import origin areas in 2013 – defined as those whose share of total Italian imports exceeds 4 per cent – the group of countries belonging to Central and Southeastern Europe plays a relevant role, too, mainly because of geographical proximity.<sup>13</sup> In our sample period, imports from these countries rose by an average of 9.9 per cent per year, only slightly below the Chinese figure (10.3). Hence, we redefine  $\Delta IC_{it}$  in (1) so as to include in  $\Delta M_{kt}^{ITA}$  also imports to Italy from Central and Southeastern Europe, while keeping the instrument group unchanged. Column 4 indicates that broadening the set of sending countries does not alter our results. Another potential drawback of our key regressor is related to the set of importing countries. Proxying the trade shock with Chinese import penetration within a single country might make more sense in the case of an economy that exhibits a very large internal market. The US, for example, seems to fully meet this requirement. When it comes to smaller developed countries, like Italy (or Germany or France), this implicit assumption is no longer obvious, and it would be reasonable to assume that competition with low-wage exporters actually takes place within a wider

---

<sup>13</sup> The list of countries includes Czech Republic, Hungary, Poland, Slovak Republic, Slovenia, Bulgaria, Croatia, Romania, Albania, Bosnia and Herzegovina, Kosovo, FYR Macedonia, Montenegro, and Serbia. At the end of the 1980s, they accounted for a relatively small (but not irrelevant) share of Italian imports (3 per cent); in 2013, at the end of our sample period, this share had grown considerably reaching 9 per cent.

market. Therefore, we re-compute  $\Delta IC_{it}$  in (1) by including in  $\Delta M_{kt}^{ITA}$  also imports from China to Italy's top five export destinations in 1992.<sup>14</sup> The estimated effect of the trade shock continues to hold (column 5). Still, a further issue with the trade exposure indicator regards the normalization of the change in imports from China. In the baseline equation (1) we follow Autor et al. (2013) and divide import change by employment in Italy in sector  $k$  measured at the beginning of the decade. In column 6, instead, imports are divided by absorption (internal production + imports – exports at the sector level) at the start of the decade, along the lines of Autor et al. (2016). The coefficient of interest is again positive and statistically very significant. The last concern about the import exposure measure is that we are not capturing the potential benefits of trade integration that may come from Italian exports to China. In Column 7, we substitute net Italian imports from China (imports – exports) for  $\Delta M_{kt}^{ITA}$  and the main result is unaffected.

Then, we check that our key coefficient is not picking up the impact of two concurrent shocks leading in turn to higher populism. The first is the other major facet of the ongoing globalization process, namely the increasing international migration towards rich countries. Hostility to immigration is justified by populist parties on the basis of the perception that foreigners pose a threat to jobs and livelihoods and a challenge to national cultures and identities. The second is the introduction of the euro in 1999. According to the anti-euro rhetoric – which, not surprisingly, has been largely embraced by the parties we classify as populist – the end of competitive currency devaluation harmed Italian exporters, generating unemployment in exporting sectors. In column 8, we control for immigration (the sample is restricted to the 2001-2013 period because of data availability), while in column 9 for the euro shock (see Section 2). In Column 10, we run our baseline regression model (equation 2) with both potential confounding factors. Reassuringly, the effect of import competition is largely confirmed.

Finally, the remaining four columns in Table 3 tackle a few additional issues. Between 1992 and 1994, Italy witnessed the outbreak of the so-called Mani Pulite scandal, a judicial investigation into political corruption. As a result of this scandal, the political system underwent a deep transformation, with the disappearance of many traditional parties including the Christian Democracy (*Democrazia Cristiana*), the main party since the end of WWII, and the Socialist Party (*Partito Socialista*), which played a very important role in supporting the former during the eighties. The 1992 election (the first one in our sample) was the last election of the long-established First Republic; from the 1994 election onwards, new forces joined the political arena, including Berlusconi's party *Forza Italia*. In column 11, we document that our finding is robust to the exclusion of the 1992 election from the sample. Column 12 is concerned with the spatial units of analysis. Our very detailed breakdown allows us to exploit a very large portion of variability. However, this might come at a cost: spillover effects among municipalities. For example, a certain trade shock may hit a municipality, but its effects may spread outside that municipality because of local production ties and worker mobility. In the end, spillovers may bias parameter estimates. To ensure that this is not the case, we aggregate all relevant variables at the level of 611 local labor markets (with an average size equal to about 97,000 inhabitants), which are much more self-contained units than

---

<sup>14</sup> Germany, France, the US, Great Britain and Spain. In 1992, the share of total Italian exports to each country was above 5 per cent and the cumulative share was 54 per cent.

municipalities as their boundaries are defined on the basis of daily commuting patterns. Again, our key estimate is confirmed. In column 13, we augment the baseline specification with area\*trend fixed effects and results are once more largely reassuring. Lastly, we test the validity of our findings to the length of first differences. The literature in the field usually uses ten-year first differences, not only because it follows Autor et al. (2013) who rely on decadal Census data, but also because economic shocks might take some time to transmit. In our data the average length of first differences is 3.5 years, lower than in Dippel et al. (2017) and Malgouyres (2017b) (11 and 5.7 years, respectively). In column 14, we replicate the benchmark regression using only the elections held in 1992, 2001, and 2013 (those nearest to the Census years): results are qualitatively similar to the full-sample case.

**Additional findings on protest vote.** In order to provide a more complete picture, it is worth investigating the possibility that import competition from China might, not only have shifted votes towards populist parties, but also have triggered some other forms of protest vote. In Table 4, we present the IV results for regression model (2) with the average annual change of the share of invalid (blank and null) ballot papers (columns 1-3) and the average annual change in voter turnout (columns 4-6) as dependent variables. It turns out that import competition exerts a positive and highly significant effect on invalid ballots – known to be an alternative way of protesting against politics and politicians, and a negative and highly significant effect on voter turnout – a well-celebrated determinant of the quality of the democratic process. In both cases, the economic size of the impact is non-negligible: the estimates reported in the columns 3 and 6 imply that a one standard deviation increase in the average annual change of the trade shock implies a variation in the dependent variables that is 7 per cent (for invalid ballots) or 5 per cent (for turnout) of the respective standard deviations.

## 5. Labor market as the transmission channel

We have established that the rise in Chinese exports generates an increase in the share of votes for populist parties, along with an increase in the share of invalid ballots and a drop in voter turnout. Instrumental variable estimations ensure that these relationships have a causal interpretation. According to the economic theory outlined in the Introduction, the transmission channels should be concerned with the redistributive effects of trade between and within countries: developed countries suffer from the upsurge of low-wage emerging exporters such as China and the negative impact is likely to affect more strongly domestic workers whose degree of substitutability for workers in low-wage countries is larger. In this Section we test whether these channels are at work in our case study.

In Table 5, column 1, we report again our baseline estimate on the effect of import competition from China on populism. In column 2, we test whether import competition from China has a negative impact on employment. To this end, we run a slightly modified version of equation (2):

$$\Delta EMP_{it} = \beta \Delta IC_{it} + X'_{it-10} \gamma + \delta_t + \gamma_{r(i)} + \varepsilon_{it} \quad (4)$$

where  $i$  indicates municipalities and  $t$  denotes Census years (2001, 2011);  $\Delta EMP_{it}$  is the ten-year change of total employment as a share of the working age population;  $\Delta IC_{it}$  is the trade shock defined as in (1) with the only difference that now  $\Delta M_{kt}^{ITA}$  is the change in imports from China to Italy in the tradeable sector  $k$  between  $t$  and  $t - 10$ ; the instrumental variable is adjusted accordingly.  $\delta_t$ ,  $\gamma_{r(i)}$  and  $X_{it}$  are defined as above. We find a negative and significant impact of Chinese import penetration on total employment: a one standard deviation rise in the import exposure shock induces a drop in the dependent variable larger than one-fifth of its standard deviation. These results suggest that even if China's competition affects directly only workers in tradeable sectors, negative effects are detectable at the aggregate level as well, probably because of spillover effects.<sup>15</sup>

Next, we examine how the China effect extends to other relevant variables: income, durable consumption, inequality. The estimating equation is analogous to previous ones and reads as:

$$\Delta y_{it} = \beta \Delta IC_{it} + X'_{it_0} \gamma + \delta_t + \gamma_{r(i)} + \varepsilon_{it} \quad (5)$$

where  $\Delta y_{it}$  is alternatively the annual change in the natural logarithm of income per taxpayer (with  $t = 2003, 2004, \dots, 2014$ ), the annual change in the natural logarithm of new car sales per capita (using 2001 Census and with  $t = 2001, 2002, \dots, 2013$ ), the annual change in the Gini index (with  $t = 2003, 2004, \dots, 2014$ ).<sup>16</sup> We document that the China import shock has a negative effect also on income, though the size of the impact is smaller than in the case of employment (Table 5, column 5): the standardized beta is 0.01. This effect on income carries over to new car sales (Table 5, column 6). Furthermore, we find evidence for a small, positive and significant impact of import competition on the Gini index (Table 5, column 6).<sup>17, 18</sup>

All in all, results in Tables 5 are consistent with the theoretical prediction according to which Italy, as a rich and developed country, is a loser in trade globalization and experienced an increase in internal income inequality.

## 6. The role of public intervention

The results presented so far depict a clear picture: the “China Syndrome” hit Italian municipalities, lowering employment, income and durable consumption, and increasing income inequality. As a reaction to heightened economic distress, voters tend to embrace populist view. But if economic insecurity is at the heart of the populist backlash, then fiscal policy might play a role as a counteracting force. In this Section, we look for empirical evidence supporting such an argument. We augment the set of regressors in equation (2) with local public spending, proxied by (i) total

<sup>15</sup> In unreported evidence (available upon request) we replicate the estimation of equation (4) with manufacturing employment as the dependent variable. As expected, we find stronger effects of import competition than those reported in Table 5.

<sup>16</sup> Note that our results on populism and on employment hold in the 2000s, too (Table 5, columns 3 and 4).

<sup>17</sup> We cannot correct directly for tax evasion. Therefore, we give more weight to more reliable data by weighting regression with weights equal to  $1 - (\text{imputed tax evasion rate})$ .

<sup>18</sup> This result is in line with Helpman (2018). He argues that, while in theory the mechanism linking trade and inequality is plausible, the empirical evidence suggests that the magnitude of the effect is rather small.

national expenditure imputed to municipalities, (ii) welfare national expenditure imputed to municipalities or (iii) current expenditure of the municipal government (see Section 2). In the last case we exclude from the sample municipalities belonging to the five regions with special autonomy (Valle d'Aosta, Trentino-Alto Adige, Friuli-Venezia Giulia, Sicilia, Sardegna), which were allowed to follow different rules, and we focus on the 2001-2013 subperiod for which the instrument based on ISP is available.

Table 6 reports the results. In Panel A the proxy for public spending at the municipal-year level is based on total national expenditure, which is available from 1995 onwards. This first proxy enters the regression with a negative sign: municipalities more exposed to public spending exhibit lower support for populist parties (columns 2 and 3). The effect of Chinese import competition is still positive and significant (columns 1 and 3). Standardized betas for trade shock and public expenditure are 0.1 and -0.04, respectively, so signaling that the latter partially offsets the former. The mitigating effect works also through an interaction term, even though with no statistical significance at the usual standards (column 4). Overall, these findings point to a clear policy implication: as far as the populist reaction is concerned, trade opening and public intervention are complements. Panel B offers an even more clear-cut picture: in municipalities benefiting of larger welfare expenditure, populism is lower (columns 2, 3) and the China effect is softened (column 4). In Panel C, local public expenditure is proxied by current spending of the municipal government, instrumented with the ISP. Again, it turns out that there is room for fiscal stimulus as a tool to counteract the China effect on populist voting (columns 2 and 3), albeit we are unable to replicate the interaction effect due to weak instruments (column 4).<sup>19</sup>

## 7. Conclusions

In recent years, populist parties have experienced a surge in support across Western developed countries. We focus on the Italian case – one the most affected countries – and contribute to the existing literature along three lines. First, we show that trade competition from low-wage countries and, in particular, from China contributes to causally explain the populist backlash. This result is robust to a number of sensitivity checks, involving, among others, the control for concurrent shocks such as immigration and the end of competitive devaluation. Moreover, we show that that protest vote also takes the form of an increase in invalid ballot papers and a drop in voter turnout. Second, to rationalize these findings, we analyze the labor market effect of the China shock and find that it lowers employment, income and durable consumption, and is positively correlated with income inequality, consistently with predictions from trade theory: the “Great Convergence” among countries went hand in hand with the “Great Divergence” within countries. Third, we turn to the policy implications of trade globalization and document that public expenditure has a counteracting effect on populism, which seems to suggest that fighting economic insecurity could be an effective tool to limit populist backlash. This last result feeds into the ongoing debate on the government's capacity to counterbalance the political consequences of globalization. For example, a recent survey

---

<sup>19</sup> Unreported evidence (available upon request) shows that when we re-run regressions in Panel A and B after excluding from the sample municipalities in regions with special status (for comparability with Panel C) results are largely confirmed.

carried out at the University of Chicago Booth School of Business highlighted large consensus among well-celebrated economists about the need of “Enacting more redistributive expenditures and policies [...] to limit the rise of populism”;<sup>20</sup> Christine Lagarde, who had just been appointed President of the European Central Bank, argued that fiscal policy is required “to respond to the threat of populism”.<sup>21</sup> More generally, it appears that sustaining public support for trade opening implies providing solutions for globalization losers.

The dependent variable is the average annual change in the populist vote share between two elections. Votes are categorized as populist following Inglehart and Norris (2016). In Panel A local public expenditure is proxied with national figure. In Panel B local public expenditures is proxied with national figure restricted to welfare-related objectives. In Panel C local public expenditure is proxied with municipal government's current expenditure instrumented by ISP (municipalities belonging to the regions with special autonomy are excluded). Standard errors are clustered at the level of 611 local labor markets. \*  $p < 0.1$ ; \*\*  $p < 0.05$ ; \*\*\*  $p < 0.01$ .

**Figure 1: Populism in some Western countries**

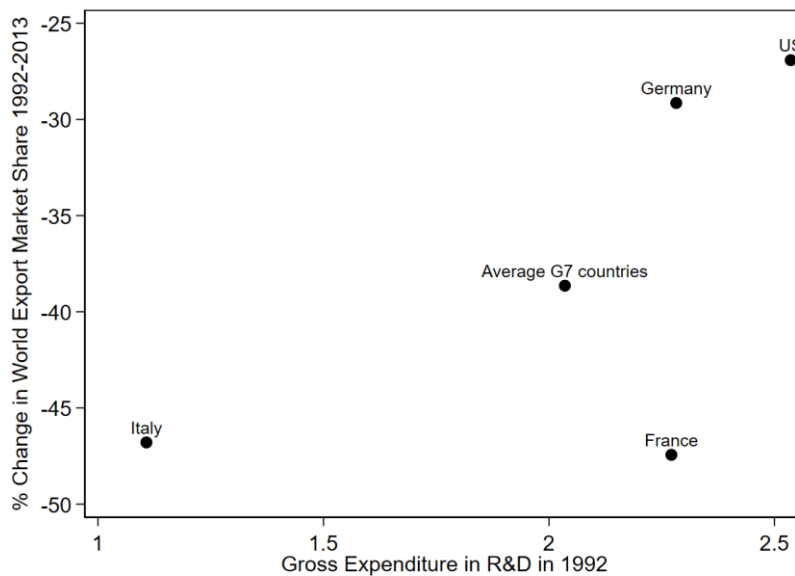

Western Europe: Aut(2017), Bel(2019), Deu(2017), Esp(2019), Fin(2019), Fra(2017), Gbr(2017), Grc(2015), Ire(2016), Ita(2018), Nld(2017), Nor(2017), Swe(2018)

**Note:** Vote share won by all populist parties in the last available parliamentary election in France (2017), Germany (2017), Italy (2018), and Western Europe. The latter aggregate includes all countries (except Switzerland) considered in Colantone and Stanig (2018) and is weighted using the 2016 population. Parties are labelled as populist based on the classification by Inglehart and Norris (2016).
