Metropolitan areas in central Poland and their impact on migration flows¹

JEL Classification: *J11, O11, R11, R23*

Keywords: *metropolitan areas, migration flows, economic development, central Poland*

Abstract: The objective of the paper is to identify subregions (NUTS 3) of the central part of Poland pretending to metropolitan areas, as well as to study their impact on the domestic migration flows. Their social and economic situations in 2008 were determined on the basis of the composite measure values. Their participation in the domestic migration flows in the period 2008-2010, considering the directions, range and intensity of flows, was also examined. Only Warsaw is the completely shaped metropolitan area in Poland. The city demonstrates the highest economic potential and therefore the strongest migration flows and dependences with other subregions. The cities of Poznań and Łódź and also the Bydgosko-Toruński subregion can be recognized as developing metropolitan areas. These subregions represent significant economic centres; however migration flows related to them demonstrate mainly regional importance.

Introduction

Regional analyses conducted emphasise the importance of metropolitan areas as essential factors of social and economic development. That results

¹ The project was co-financed by Nicolaus Copernicus University in Toruń within a UMK research grant no. 1481-E.

from the fact that metropolitan areas are characterised by a significantly higher development dynamics if compared with non-metropolitan areas. Nowadays, metropolitan areas function as the world's most important economic, scientific, cultural, administrative, and political centres (see Maik 1997, Gawryszewski, Worcelli, Nowosielska 1998, Gorzelak, Smętkowski 2005, Markowski, Marszał 2006, Gorzelak, Tucholska (ed.) 2007, Jałowiecki 2007, Ładysz 2009, Heffner 2011). The development of innovation and creativity occurs within their areas and by means of diffusion they affect the whole of the adjacent region and, thereby, contribute to its development.

Other benefits of metropolitan areas include a better developed transport infrastructure, diversified labour market, access to economic (technological parks, business incubators, centres of technology transfer, delivery institutions, financial institutions, etc.) and social (schools, universities, hospitals, cultural centres, etc.) infrastructure. Concentrating economic functions, work places and services rendered in metropolises affects an increase in ties between the central area and the nearest environment, and the whole region. It attracts not only capital and companies but also people, which results in more intense migration flows.

The subject literature indicates abundant definitions of metropolitan areas, their classifications, approaches, and methods of delimitation (see Smętkowski, Jałowiecki, Gorzelak 2009, Markowski, Marszał 2006). A metropolitan area is usually defined as a settlement network with its centre represented by a strongly urbanized city (with over 500 thousand inhabitants) that is economically well developed. Poland's capital city – Warsaw, is an already shaped metropolitan area (see Korcelli-Olejniczak 2007, Gawryszewski, Korcelli, Nowosielska 1998), but there can be found other Polish cities that are currently strengthening their metropolitan functions. Determining them, however, requires redefining a metropolitan area for Polish realities. One of the crucial criteria that allows identifying metropolitan areas in Poland is the consideration of economic premises, as well as measuring the intensity and direction of migration flows.

The present paper attempts to identify metropolitan areas in the central part of Poland, as well as to study their impact on the domestic migration flows in the years 2008-2010, and also to analyse the scale and conditions of these processes. The paper is the continuation of the research conducted by its authors on the phenomenon of Poland's internal migration flows and its conditions (see Matusik, Pietrzak, Wilk 2012, Pietrzak, Drzewoszewska, Wilk 2012, Pietrzak et al. 2012, Pietrzak, Wilk 2013, Pietrzak, Wilk, Chrzanowska 2013, Pietrzak, Wilk, Matusik 2013a, 2013b, Pietrzak, Wilk,

Siekaniec 2013, Wilk, Pietrzak 2013, Wilk, Pietrzak, Matusik 2013, Biczkowski et al. 2014, Pietrzak, Wilk 2014, Pietrzak et al. 2014).

Methodology of the research

Globalisation processes and Poland's accession to the European Union have resulted in the dynamic growth of the national economy. Such a situation has fostered the strengthening of the metropolitan functions of the country's largest cities and the competitiveness of the regions in which they are situated. Poland is characterised by a distinct territorial disparities in the level and rate of regional development. Significant economic disproportions are displayed by the regions situated in the central part of the country which comprise the Kujawsko-pomorskie, Wielkopolskie, Łódzkie, Mazowieckie, and Świętokrzyskie regions. Due to their geographical location, the shape of the area, concentration of natural resources, regions situated in central Poland fulfil various (e.g., tourist, manufacturing, demographic base, etc.) functions. The regions can be defined as industrial, rendering services and agricultural.

The level of regional development including the economic potential is conditioned by economic profile, level of productiveness, entrepreneurship, inflow of foreign capital, predisposition to attract investments, companies' standing and the absorptiveness of the labour market (see see Strahl (ed.) 2006, Müller-Frączek, Pietrzak 2008, Müller-Frączek, Pietrzak 2009a, 2009b, Bal-Domańska, Wilk 2011). The diversified level and rate of social and economic development in Poland impacts the formation of economically strong centres, both within regions and within the whole country, which display the features of metropolitan areas.

The evaluation of the regional differentiation of the economic situation in central Poland was made on the level of subregions (NUTS 3). The analysis was conducted based on the set of diagnostic features contained in Table 1 and the data on the situation in the subregions concerns the year 2008. That year was the time when Poland started to be affected by the world financial and economic crisis which manifested themselves in the economic slowdown. These processes were accompanied by a fall in the intensity of migration flows and the group of target migration regions was narrowed.

The idea of the taxonomic development measure (TDM) was applied in the analysis. TDM allows analysing all features at the same time, as well as making synthetic evaluation of social and economic situation in subregions (see see Grabiński, Wydymus, Zeliaś 1989). The construction process of

the measure consisted of a few stages. Firstly, the preferences of variables were determined. Almost all of the variables function as stimulants. The exception is the unemployment rate which is a destimulant and its high values should be evaluated as negative.

Table 1. Features describing economic potential of subregions

Diagnostic variables	Impact direction
Gross added value per employed person (in PLN)	Stimulant
People conducting economic activity per 100 working-age people (entity)	Stimulant
Share of commercial companies with foreign capital per 100 national economy entities in the private sector (registered in REGON) (%)	Stimulant
Investment outlays in enterprises per capita (PLN)	Stimulant
Share of persons employed in the service sector (market and non-market) in employed persons (%)	Stimulant
Average monthly gross wages and salaries (PLN)	Stimulant
Share of registered unemployed persons in <i>working-age persons</i> (%)	Destimulant

Source: Own preparation.

Next, the coordinates for the pattern object were determined. The upper pattern of development was taken as a reference point. The maximum values noted in 2008 were considered beneficial for stimulants and the minimum ones for destimulants. Then, the normalization of the changeable values was performed by means of the unitization with zero minimum. The character of the variables was unified by changing a destimulant into a stimulant and that was achieved by subtracting its value from 1.

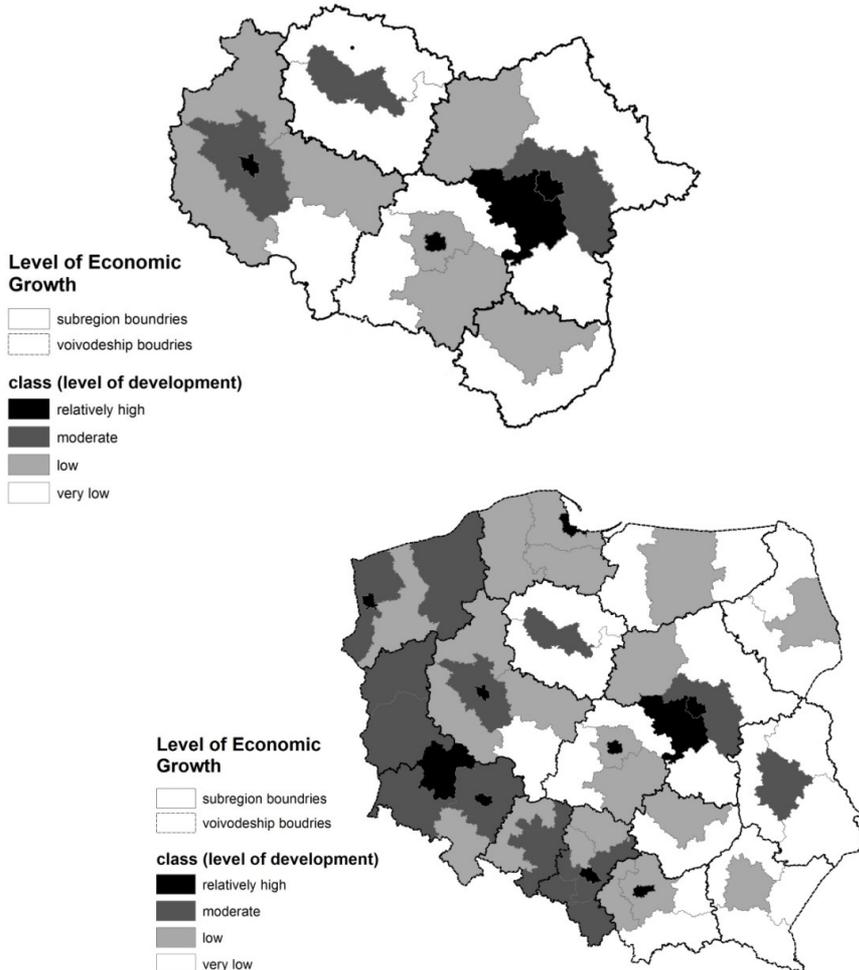

The distance between each object (subregion) and the pattern object was identified by means of Euclidean distance. Also, for each subregion the value of TDM was designated by means of Hellwig's method (see Hellwig 1968). The interval of measure values was divided by means of the 3-means (see Nowak 1990) method into four classes representing relatively high, moderate, low and very low levels of economic development.

Economic growth in central Poland

Results of the classification of sub-regions are shown in Figure 1. The outcome of the research confirmed significant heterogeneity of the central area of Poland. The highest value of the measure within that area was noted

in the city of Warsaw (0.987), and the lowest in the Sandomiersko-kędrzejowski subregion (0.119). Apart from Warsaw, the class of the highest level of development is also represented by the city of Poznań, the Warszawski zachodni subregion, and by the city of Łódź. Other examples of economically distinctive subregions include the independent Bydgosko-toruński subregion, the Poznański and Warszawski wschodni subregions.

Figure 1. Economic situation in subregions of central Poland in 2008

Source: Own preparation based on data BDL GUS.

Warsaw represents an already formed metropolis, however, while looking for subregions which display the features of metropolitan areas in

central Poland, it is necessary to consider the intensity and directions of migration flows. More intense migration flows, particularly significant inflows and a positive net migration in the largest urban areas, indicate a growing position of the central area, if compared with the whole of the country.

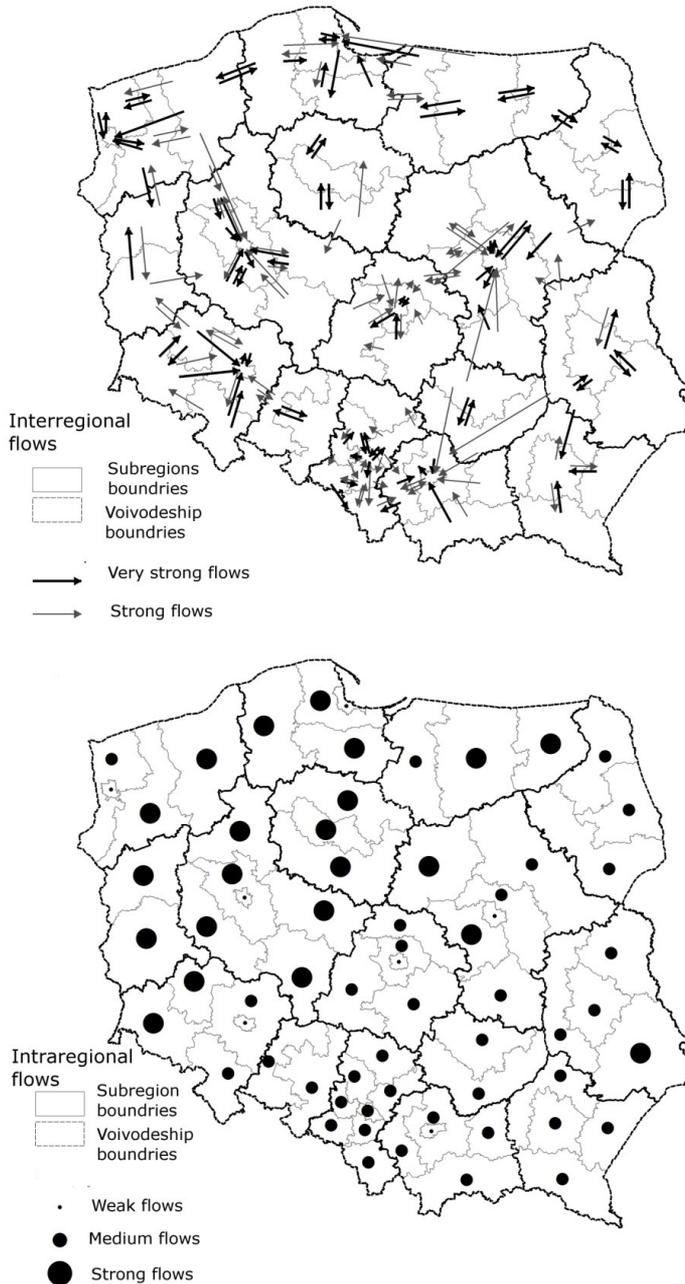

Participation of central Poland's regions in domestic migration flows

A significant feature of migration flows is a delayed and stretched in time reaction to changes in the economic cycle. The fall in the intensity of internal migrations was observed not only in 2008 but also in the following years of the world crisis. Therefore, migration flows observed in the years 2008-2010 were considered throughout the whole period as aggregated values. In order to ensure the comparability of results, values were divided by the average population numbers in the 2008-2010 period. The directions of interregional flows and the intensity of flows within subregions (intra-regional flows) were analysed.

The values of the intra-regional flows ratio were divided into three classes equal in numbers. In the case of the interregional migration flows, with a view to maintaining clarity, five selected groups of flows were determined. Classes were created based on specific values of centiles. The class of 'very strong flows' was ascribed to 2% of the largest domestic migration flows (the values of the ratio were contained in the interval (C98, max)). The 'strong flows' class was set up for the interval (C96, C98). Also, a class of 'medium flows' was created and it was divided into three subclasses, i.e., 'medium flows (class 1)' for the interval (C94, C96), 'medium flows (class 2)' for the interval (C92, C94), and 'medium flows (class 3)' for the interval (C90, C92). Figures 2 and 3 show the values of intra-regional flows and the directions of strong and medium migration flows between subregions.

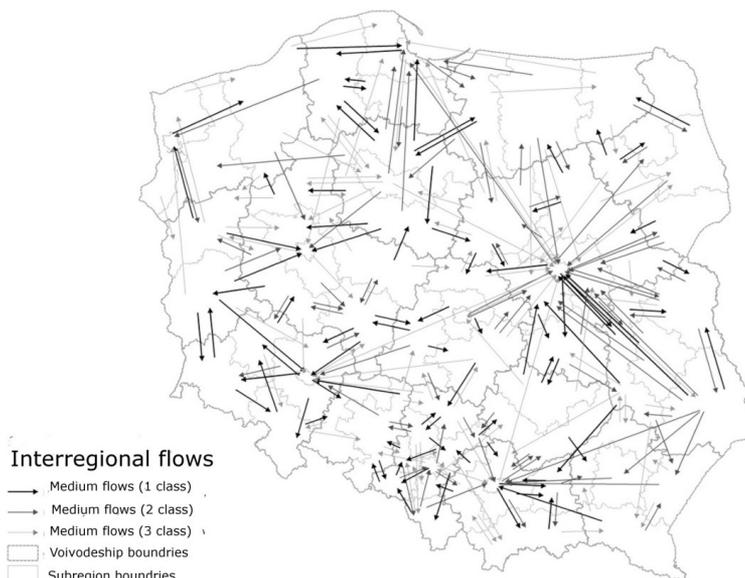

The largest provincial cities were included in the class of weak intra-regional flows. As shown by public statistics, the size of flows is recorded at the level of 0. It results from the fact that in accordance with the methodology applied by the Main Statistical Office (GUS), migration flows within territories of cities with the district rights are not treated as migration flows since the administrative borderlines of communes are not crossed. For that reason the cities of Poznań, Łódź, Warsaw, Wrocław, Cracow and Szczecin do not display intra-regional migration flows.

Figure 2. The intensity of migration flows within subregions in Poland and of strong flows between subregions

Source: Own preparation based on data BDL GUS.

Figure 3. The directions and intensity of medium migration flows between subregions

Source: Own preparation based on data BDL GUS.

The strongest intraregional flows occur in the subregions of the Kujawsko-pomorskie and Wielkopolskie regions as well as in the western part of the Mazowieckie region. The subregions of the Łódzkie and Świętokrzyskie regions and of the eastern part of the Mazowieckie region display considerably lower intensity of intraregional migration flows.

In terms of migration flows the most hermetic region is the Kujawsko-pomorskie region. The directions of the largest interregional flows in this region indicate the occurrence of intense migration flows with the participation of the Bydgosko-Toruński subregion. The subregion participates in the bilateral exchange of population with the Włocławski and Grudziądzki subregions. Strong migration flows crossing the borderlines of the Kujawsko-pomorskie region were identified merely by the Włocławski subregion. The situation in the Bydgosko-toruński region is peculiar since there are two leading centres there – the city of Bydgoszcz and the city of Toruń. In the future a bipolar metropolitan area may be created in the region with its two core area centres.

Analysis of medium migration flows indicates essential relations holding between the Bydgosko-Toruński subregion and the subregions of the adjacent regions, as well as between Warsaw, Poznań and the Gdański

and Trójmiejski subregions (the Pomorskie region). It may be stated then that the Bydgosko-toruński subregion impacts the whole of the country. The strong migration flows with the participation of the Bydgosko-toruński subregion result from its good economic situation and prove the development of the relations that are typical of metropolitan areas.

The strong economic position of the Wielkopolskie region translates into more intense migration inflows of people from the neighbouring regions (the Lubuskie, Pomorskie and Kujawsko-pomorskie regions) to the region. However, the most intense migration flows can be observed between the subregions of the Wielkopolskie region. Strong bilateral migration flows can be observed between the city of Poznań and the Poznański subregion that surrounds it. The strong economic position of Poznań causes significant flows between it and the remaining subregions of the Wielkopolskie region, as well as bilateral migration flows with the participation of the Poznański subregion and its neighbouring subregions.

Medium migration flows occurring in the Wielkopolskie region target primarily those subregions which are adjacent to the region or occur within the region. The impact of Poznań on migration flows, despite its strong economic position, is rather regional than nationwide. It must be stated, however, that Poznań functions as the core of that developing metropolitan area.

The city of Warsaw, which is Poland's largest economic centre causes bilateral migration flows between the subregions of the nearest location of the Mazowieckie region, as well as the Skierniewicki subregion of the Łódzkie region. Also, there can be seen strong one-direction flows between the subregions of the Mazowieckie region and they head towards Warsaw. Warsaw's strong position initiates inflows from the Kielecki subregion (the Świętokrzyskie region) and the Puławski subregion to the Mazowieckie region. The analysis of the migration flows of medium intensity confirms the existence of strong ties between Warsaw and other regions of the country. In addition, it confirms Warsaw's being the core of that already shaped metropolitan area. It can be stated that this area displays similar metropolitan functions to those that can be seen in well-shaped metropolitan areas of developed countries.

The Łódzkie region has moderate intraregional flows, however, we can observe there strong interregional flows. The main target for migration flows is the city of Łódź which participates in the bilateral exchange of population with other subregions of the Łódzkie region. Also, we can observe there one-direction flows from the neighbouring subregions of the Łódzkie region to the Łódzki subregion (surrounding the city of Łódź). Strong relations holding between the Łódzkie region and the Mazowieckie

region translate into intense two-direction exchange of populations of the adjacent subregions of these two regions.

The analysis of migration flows of medium strength conducted for the Łódzkie region also shows some interesting dependencies. The flows between the subregions of the region are evident. However, flows of medium strength move from the city of Łódź to the city of Warsaw and the Warszawski zachodni subregion, from the Piotrkowski subregion to the Warszawski wschodni subregion, from the Sieradzki to the Częstochowski subregion, from the Sieradzki subregion to the city of Wrocław, from the Kielecki subregion to the city of Łódź, from the Piotrkowski subregion to the city of Wrocław and the Częstochowski subregion, and from the Częstochowski subregion to the Sieradzki and Piotrkowski subregions. Due to its economic position and the intensity of migration flows, the city of Łódź can be deemed the core city of this developing metropolitan area of the Łódzkie region.

The Kielecki subregion is the most active in migration processes throughout the Świętokrzyskie region. Apart from the bilateral exchange of population with the adjacent Sandomiersko-jędrzejowski subregion, we can see strong outflows from the Kielecki subregion to two subregions of the neighbouring regions, i.e., to the cities of Warsaw and Cracow. This shows a weak ability of attracting migration flows by the subregions of the Świętokrzyskie region.

In the case of the Świętokrzyskie region the bilateral migration flows between the Kielecki subregion and the Radomski subregion are of medium strength. Moreover, other flows that were noted moved from the Kielecki subregion to the Warszawski zachodni subregion, from the Sosnowiecki subregion to the Sandomiersko-jędrzejowski subregion, and from the Sandomiersko-jędrzejowski subregion to the Tarnobrzeski and Krakowski subregions. The weak socio-economic situation of the major city (Kielce) and other parts of the region indicates the lack of possibilities of creating the metropolitan area.

Conclusions

The article presents the analysis of the social and economic situation of subregions situated in central Poland based on the data from 2008. Also, it commented on the migration flows with their participation in the period 2008-2010. Considering the economic importance of those subregions for the national economy and the migration flows, an attempt was made to define those subregions that pretend to metropolitan areas.

Warsaw's strong economic position and its powerful impact cannot be compared to any other subregion of central Poland. Undoubtedly, Warsaw is a completely shaped metropolitan area impacting the whole country. Despite the downward trend in the economic cycle, the economic situation of Warsaw and its range of impact have remained the strongest in the country. This proves its established position and its role of the major metropolitan centre in Poland.

Taking into consideration the economic situation, as well as the strength and range of spatial dependence, the following can be recognized as metropolitan areas: the city of Poznań, the city of Łódź and the Bydgosko-toruński subregion. These subregions, however, do not play as significant role in Poland's migration flows as the city of Warsaw. Migration flows related to them are significant but they mainly demonstrate regional importance.
