QUALITY OF INSTITUTIONS AND TOTAL FACOR PRODUCTIVITY IN EUROPEAN UNION

Abstract: The key challenge for medium- and long-term policy in European Union countries is to use the potential of knowledge-based economy (KBE), which is a condition for maintaining high total factor productivity in Europe. For this reason, the relationship between quality of institutional system and total factor productivity in the EU countries has been examined. The quality of institutional system is defined here from the perspective of incentives that influence the use of the potential of KBE. In order to determine the level of effectiveness of the institutional system in the analyzed countries the method for linear ordering of objects was applied based on data from Fraser Institute. The main hypothesis of the article was formed as follow: the quality of institutional system in the context of KBE has significant influence on the level of total factor productivity in the EU. In order to verify the hypothesis, the parameters of the Cobb-Douglas production function were estimated, which allowed to evaluate TFP for EU countries. The calculation made in the article was based on Eurostat data. Then, the identification of the relationship between the quality of institutional system and the level of TFP was made with the application of panel model. The research made for the years 2000-2010 allowed to verify the hypothesis.

Keywords: KBE, TFP, quality of intuitions, European Union, panel model

1. Introduction

The efforts devoted to the research on the determinants of Total Factor Productivity (TFP) growth both at international (Coe and Helpman, 1995, pp. 859-887, Coe *et al.*, 2008; Aiyar and Dalgaard, 2005, pp. 82-102) and regional level for example for Poland (Tokarski 2008, pp. 38-53; Tomaszkiwicz and Świeczewska 2011, pp. 36-55) have been significant for last decade. However, due to many structural changes of the world economy that have been observed for last years, the famous postulate of Edward Prescott on the need to strengthen the research intensity on the theory of TFP is still valid (see Presott, 1998, pp. 525-551). This is especially important in the context of growing role of many intangible and difficult to measure factors that affect productivity differences between developed countries in globalized knowledge-based economy (KBE) (see: van Ark, 2014, pp. 17-19; Fraumeni, 2014, pp. 20-21). This article can be treated as a proposition of research in this field. Thus, the aim of the paper is to analyze TFP in European Union countries in the years 2000-2010 and to evaluate

¹ Nicolaus Copernicus University, Department of Economics, e-mail: adam.balcerzak@umk.pl

² Nicolaus Copernicus University, Department of Econometrics and Statistics, e-mail: michal.pietrzak@umk.pl

the influence of quality of institutions in the context of the KBE on the productivity growth in the years 2000-2010.

The first hypothesis of the article was formed as follow: the quality of institutional system in the context of the KBE has significant influence on the level of TFP in the EU countries.

The second hypothesis of the research was referring to the institutional literature that pointed to many important weakness of institutional order in former transformation countries of Central Europe and the concept of institutional lag in the case of these economies, especially in in regard to formal regulations and governance influencing the speed of diffusion of technology and new organizational ideas. As a result, the second hypothesis was formed as follow: Countries that joined European Union after 2004, under the conditions of improving quality of their institutions for the KBE, can use the potential of reducing institutional lag for increasing the speed of TFP growth more than proportionally in comparison to “old” member states. This factor is important from the perspective of guidelines for policy that is aimed at increasing the speed of convergence process in the EU. The article is a continuation of previous research presented in Balcerzak and Pietrzak (2015a, pp. 71-91; 2015b, 2016).

2. Total Factor Productivity in European Union Countries

Obtaining high level of productivity and improving the effectiveness of utilization of production factors is considered as an important middle and long term aim of economic policy in the European Union (European Commission, 2010; Forgo and Jevcak 2015). Based on the aim and objective of this paper the analysis of TFP changes for 24 European Union countries for the years 2000-2010 was done.

Luxemburg, Malta, Cyprus and Croatia were not included in the research. The first three countries were excluded due to lack of data, additionally Croatia became a member state in 2013. In the analysis the following data was used: total employment (annual averages in thousands of persons), real gross value added (million euro, reference year 2000) and gross fixed capital formation (million euro, reference year 2000). Eurostat was the source of the data.

The starting point of the research was the assessment of the productivity level for all the countries in the years 2000-2010 based on the Cobb-Douglas production function. The Cobb-Douglas production function after taking the logarithm of both sides of equation, can be written as follows:

$$\ln GVA_{it} = \eta_i + gt + \alpha \ln GCF_{it} + (1 - \alpha) \ln E_{it} + \varepsilon_{it} \quad (1)$$

Where:

GVA_{it} – vector of real gross value added in the country i and the period t ,

$GFCF_{it}$ – vector of gross fixed capital formation in the country i and the period,

E_{it} – vector of employment in the country i and the period,

η_i – vector of values of individual effects that determine the average value of total factor productivity, in the period t ,

t – time trend,

α – elasticity of labor productivity to the capital,

g – rate of technological progress in the sense of Hicks,

ε_{it} – a vector of disturbances.

After subtracting the expression $\ln(E)$ from both sides of equation (1), equation (2) is obtained. It describes the level of labor productivity relative to the capital to labor ratio.

$$\ln GVA / E_{it} = \eta_i + gt + \alpha \ln GCF / E_{it} + \varepsilon_{it} \quad (2)$$

Where:

GVA/E – vector of value GVA/E – labor productivity,

$GFCF/E$ – vector of the capital to labor ratio,

The remaining variables are understood in the same way as in the case of equation 1.

In the literature one can find many empirical approaches to evaluating TFP (see. Welfe (ed.) 2007; Severgnini and Burda, 2010, pp. 447-466; Gehringer *et al.*, 2014). In the article the method proposed by Tokarski was applied. Estimation of parameters of model (2) for labor productivity enables to determine the value of total factor productivity TFP_{it} for EU countries. To calculate TFP_{it} the estimated value of parameter α is used. It can be done based on the formula (see Tokarski, 2008, pp. 39-53):

$$TFP_{it} = \frac{GVA / E_{it}}{(GFCF / E_{it})^{\alpha}} \quad (3)$$

The general assumption commonly used in many proposals for estimation of TFP at the national or regional level is the application of homogeneous production functions for all the countries or regions. However, in the case of European Union in spite of the convergence process the member countries are still characterized by significant development differences. There are relatively big differences in labor productivity and the factors that can influence TFP. As a result, the analyzed countries are heterogeneous. The most obvious structural differences can be seen between so called “old” and “new” member states. Thus, the

assumption on homogeneous production functions is unrealistic here. In order to face the problem of heterogeneity, the authors divided the EU countries into two groups – the “old” member states and the once that joined UE after the year 2004. As a result in the case of the model for labor productivity (equation 2) separate parameters α_1 and α_2 for „old” and „new” member states were introduced, which can be written as follows³:

$$\ln GVA / E_{it} = \eta_i + gt + \alpha_1 \ln GCF / E_{it}^1 + \alpha_2 \ln GCF / E_{it}^2 + \varepsilon_{it}, \quad (4)$$

Where:

α_1 and α_2 – elasticity of labor productivity to the capital to labor ratio for the group of “old” and “new” member states respectively.

The remaining variables are understood in the same way as in the case of equation 1 and 2.

Additionally, the model given with equation 4 was estimated with panel model FE estimator with individual effects in order to observe the country-specific factors. The results of the estimation of the parameters of the model can be found in table 1. Individual effects for all 24 countries were statistically significant, which is consistent with previous argumentation. The estimations of parameters α_1 , α_2 and g were statistically significant too⁴. The value of estimates of the parameter α_1 and α_2 indicate that flexibility of labor productivity to capital to labor ratio equals 0,129 in the case of the countries that joined EU before 2004 and 0,290 for “new” members. The value of estimate of the parameter g at the level 0,017 indicates that the European Union economies are characterized with 2% rate of technological progress in the sense of Hicks. These results are generally consistent with previous research both at national (Gehring *et al.* 2014; Severgnini and Burda, 2010, pp. 447-466) and regional level in the case of Poland (Dańska-Borsiak and Laskowska, 2012, pp. 17-29; Tokarski, 2008, pp. 38-53; Tokarski, 2010, pp. 23-39).

³ The components of the vector GCF / E_{it}^1 make the value of capital to labor ratio for the countries in the first group and 0 otherwise. A similar situation occurs in the case of the vector GCF / E_{it}^2 .

⁴ The statistics for Durbin-Watson test points to statistically significant autocorrelation in the residuals.

Table 1. The results of estimation of parameters of panel model FE with individual effects for labor productivity

Parameter	Estimate	Standard error	Parameter	Estimate	Standard error

Source: own estimation based on Eurostat data.

The estimated value of parameter α_1 and α_1 enable to estimate logarithm of TFP_{it} for every country in the years 2000-2010 according to the formula:

$$\ln TFP_{it} = \ln GVA / E_{it} - \hat{\alpha}_j \ln GCF / E_{ij} . \quad (4)$$

Table 2 presents the logarithm of TFP for the years 2000 and 2010 and the percentage change of this value in the period 2000-2010. Additionally table 2 shows the results of grouping the countries into classes which was done with application of natural breaks method. The results presented in figure 1 confirm the heterogeneity between “old” and “new” members states.

Source: own estimation.

2. Quality of institutions in the context of knowledge-based economy as a determinant of total factor productivity

The middle and long term growth potential of developed countries is currently dependent on the ability to use potential of the KBE (Welfe (ed), 2007; Balcerzak, 2009b, pp. 711-739, OECD, 1995; Ciborowski, 2014, pp. 57-72; Wronowska, 2013, pp. 71-80). Empirical research in the case of developed economies that have been done for last two decades confirmed the influence of institutional conditions affecting transaction costs of technological changes on the number of enterprises, which are able to use new ideas and knowledge effectively and to achieve further technological breakthroughs (OECD, 2001; McKinsey Global Institute 2002). Thus, the quality of institutions in the context of the KBE should be a significant factor influencing total factor productivity in the case of developed countries. The verification of the influence of this factor is the main objective of this analysis. Its confirmation, from the policy guidelines point of view, means that in the reality of the KBE the creation of high quality institutions and their constant improvement should be treated as an essential condition for maintaining high rate of productivity growth⁵.

The analysis of empirical research in the context of theory of new institutional economics enables to indicate four fundamental segments of institutional systems, which on the one hand can be modified by governments in relatively short time, and which on the other hand have significant influence on the speed of technological change⁶. Additionally based on the arguments of new institutional economics, high quality institutions are defined here as the once that tend to lower the transaction costs of technological progress and diffusion of new organizational ideas.

The first segment of institutional system is the effectiveness of legislation influencing entrepreneurship. High level of entrepreneurship is conducive to increasing the supply of companies with high growth potential and increases the likelihood of the emergence of new innovative start-ups.

The second institutional segment relates to the effectiveness of juridical system in keeping low level of transaction costs and supporting effectiveness of market mechanism. Formal

⁵ From the institutional perspective the analysis proposed in the research concentrates on the institutions that can be influenced by policy action in relatively short or middle term (Williamson, 2000, pp. 595-613; North, 1994, pp. 359-368). The influence of institutions that are the result of long term evolutionary process is not the subject of the analysis.

⁶ More specific discussion on the research, which gave the theoretical and empirical background for pointing these segment of institutional systems as an important elements of institutional matrix influencing the possibility of utilization of potential of the KBE is available in Balcerzak, Pietrzak (2016, 2015, pp. 71-91), Balcerzak (2015, s. 51-63).

regulation that reduce the level of transaction costs favours the elimination of formal barriers to the diffusion of new organizational and technological solutions in the economy.

The third segment of institutional system is the competitive pressure and effectiveness of labour markets. The high level of competitive pressure under conditions of relatively effective labor markets creates incentives for reorganization activities, which is conducive to improving microeconomic efficiency of enterprises. It increases the potential of enterprises that are able to find and implement new technological and organizational solutions.

The fourth institutional segment refers to financial markets institutions, which should act as a stimulator of development of enterprises with high growth potential. The financial markets should support a faster reallocation of capital from industries with low to new sectors with high growth potential.

These four instructional segments can be treated as the incentive pillar of the concept of pillars of the KBE according to the World Bank (see Chen and Dahlman 2005, 2004, Madrak-Grochowska 2015, 7-21).

For the identified key institutional segments, the authors selected a set of diagnostic variables, which are presented in Table 1. Detailed data for all the variables were obtained from the database of Fraser Institute⁷. Due to the design of the database all diagnostic variables were stimulants with the values from 0 to 10. It should be emphasized that the variables presented in table 1 enable to quantify the quality only of the segments of institutional system, which are essential in the context of a country's ability to exploit the potential of the KBE. This research should not be interpreted as a proposal for holistic quantification of all segments of institutional matrix influencing economic activity and welfare in the analyzed countries (see more Gruszewska, 2011, pp. 103-120).

Table 3. The potential variables concerning quality of institutions from the perspective of KBE potential

Y₁ – formal regulations influencing entrepreneurship
X _{1t} ¹ – Administrative requirements for entrepreneurs
X _{2t} ¹ – Bureaucracy costs for entrepreneurs
X _{3t} ¹ – The cost of starting business
X _{4t} ¹ – Extra payments/bribes/favouritism
Y₂ – effectiveness of juridical system in keeping low level of transaction costs and supporting effectiveness of market mechanism
X _{1t} ² – Judicial independence
X _{2t} ² – Impartial courts

⁷ <http://www.freetheworld.com/reports.html> (1.10.2014).

X_{3t}^2 – Protection of property rights
X_{4t}^2 – Integrity of the legal system
Y_3 – competitive pressure and effectiveness of labour markets
X_{1t}^3 – Revenue from trade taxes (% of trade sector)
X_{2t}^3 – Mean tariff rate
X_{3t}^3 – Standard deviation of tariff rates

X_{2t}^4 – Interest rate controls/negative real interest rates

Source: own work based on the discussion presented in Balcerzak (2015, pp. 51-63, 2009a, pp. 71-106, 2009b, pp. 711-739), Balcerzak and Pietrzak (2016), Balcerzak and Rogalska (2008, pp. 71-87).

In the next stage, the ability of the variables to differentiate the objects was verified. Then, based on the diagnostic variables describing discussed four segments of instructional system a taxonomic measure of development TMR_{it} was calculated. The measure TMR enables to evaluate quality of institutions for 24 EU countries for the years 2000-2010. The applied method of taxonomic measure of development was proposed by Zdzisław Hellwig 1968 (1968, pp. 307-327; 1972, pp. 131-134). It is based on the comparison of distance of the object from a pattern of economic development. The application of the method enables to order the objects and divide them into homogenous classes. The value of taxonomic measure of development is influenced by many variables describing different elements of a multivariate phenomenon, thus it enables to measure it synthetically.

The value of taxonomic measure of development TMR_{it} was evaluated in two stages. At the first stage, after normalization of the values of the variable with classic normalization formula, based on the Hellwig's method the values of TMR_{it}^k for every institutional segment pointed in table 1 was calculated. In the case of every variable the pattern of economic development was set as a maximum value for the years 2000-2010. As a result a fixed pattern of development was used here, which enabled to compare dynamically the final results in the

whole period⁸. The values of four measures for every institutional segment were calculated: TMR_{it}^1 describing formal regulations influencing entrepreneurship, TMR_{it}^2 measuring the effectiveness of juridical system in keeping low level of transaction costs and supporting effectiveness of market mechanism, TMR_{it}^3 for competitive pressure and effectiveness of labour markets, and TMR_{it}^4 for financial markets institutions as a stimulator of development of enterprises with high growth potential.

In the second stage, an arithmetic mean for all the four measures TMR_{it}^k was calculated according to the following formula:

$$TMR_{it} = \sum_{k=1}^4 TMR_{it}^k / 4, \quad (5)$$

Where:

i – index for the object (country),

t – index for time.

Based on the values of TMR_{it} the European Union countries were grouped to one of five classes. As in the case of TFP it was done with application of natural breaks method. Some sets of countries, which are relatively homogenous from the perspective of quality of intuitions in the context of the KBE, were obtained. The results for the year 2000 and 2010 are presented in table 4 and figure 2.

Table 4. The values of TMR for quality of institutions in EU countries in the year 2000 and 2010

2000			2010			2000-2010		
Country	TMR	Class	Country	TMR	Class	Country	Percentage difference	Class
United Kingdom	0,78	5	Denmark	0,81	5	Romania	65,25%	5

Bulgaria	0,41	1	Slovenia	0,46	2	Spain	-15,16%	1
Romania	0,31	1	Greece	0,38	1	Germany	-15,53%	1

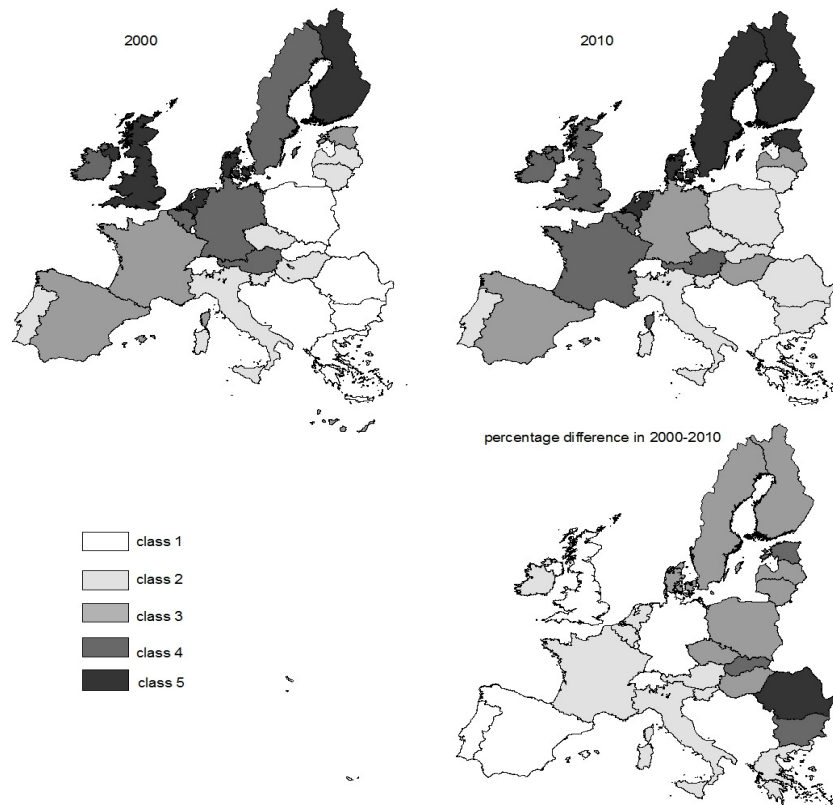

Source: own estimation based on the data from Fraser Institute.

As it could be seen in the case of TFP presented in table 1 and figure 2, the results presented in table 4 and figure 2 confirm analogous heterogeneity between UE countries in the case of quality of institutions for the KBE. The “old” member states are generally grouped in 5 and 4 classes, whereas the “new” member states with the exception of Estonia in 2010 can be found in classes from 3 to 1.

The highest values of TMR for quality of institutions in the context of the KBE were obtained by Scandinavian countries, grouped in class 5. Then, in classes 4 and 3 one can find Austria, France, Germany, and Spain. The southern European countries Portugal, Italy and Greece are characterized with lower quality of institutions for the KBE.

Central European “new” member states are grouped in classes 3 to 1, with the lowest values of TMR for Poland, Bulgaria and Romania. As a result, due to “the benefits” of institutional lag and institutional convergence process in the analyzed period the biggest improvement in the sphere of quality of institutions was obtained by the countries that joined UE after 2004 especially Romania, Bulgaria, Slovakia and Estonia (see more Balcerzak, 2011, pp. 17-34).

Figure 2. Quality of institutions for KBE in the UE countries in the year 2000 and 2010

Source: own estimation based on the data from Fraser Institute.

The calculated values of TMR were used in the next stage of the research, where the impact of the level of quality of institutions on TFP was examined. For this purpose a specification of a panel model FE with individual effects was done. The model was written with equation⁹:

$$\ln FTP_{it} = \eta_i + gt + \beta_1 TMR_{it}^1 + \beta_2 TMR_{it}^2 + \varepsilon_{it}, \quad (6)$$

Where due to the heterogeneity of the analyzed countries separate parameters β_1 and β_2 were used for two groups of economies. As the dependent variable logarithm of TFP and as independent variables logarithm of TMR_{it}^1 and TMR_{it}^2 were applied.

⁹ The components of vector TMR_{it}^1 consist of the values of TMR for the first group of „old” member states and 0 otherwise. A similar situation occurs in the case of the vector TMR_{it}^2 and the second group of “new” member states.

Table 6. The results of estimation of parameters of panel model FE with individual effects for determinants of TFP

Parameter	Estimate	Standard error	Parameter	Estimate	Standard error
β_1	0,379	0,229	g	0,018	0,003
β_2	0,898	0,280	-	-	-
Individual effects	Estimate	Standard error	Individual effects	Estimate	Standard error
Austria	3,289	0,169	Ireland	3,374	0,172
Belgium	3,362	0,161	Italy	3,306	0,127
Bulgaria	1,070	0,127	Lithuania	1,697	0,134

[all the parameters are statistically significant with 5% significance level]

Source: own estimation based on Eurostat data.

The results of estimation of the values of parameters of panel model (6) are presented in table 6. The parameters for individual effects for all the countries, the parameters β_1 and β_2 were statistically significant¹⁰. Positive values of estimation of the parameters β_1 and β_2 at the level 0.379 and 0.898 confirm the significant influence of quality of institutions in the context of the KBE on the level of TFP in the case of both groups of “old” and “new” member states. This allows to verify the first hypothesis of the research. Additionally, the higher value of parameter β_2 for “new” member states can indicate that in the case of effective institutional policy and reforms of regulations, which will lead to significant improvement of quality of institutors in the context of the KBE, the “new” member states would be able to improve their TFP more than proportionally in relation to “old” member states. This factor can become significant contributor in the process of reducing development differences and supporting convergence process of European Union Countries. This result is consistent with the previous analysis of influence of quality of institutions for the KBE on the convergence process in Europe, which was done by the authors within conditional β -convergence framework (Balcerzak and Pietrzak 2015b). Thus, the outcome of the analysis enable to verify the second hypothesis of the research.

¹⁰ The statistics for Durbin-Watson test points to statistically significant autocorrelation in the residuals.

3. Theoretical reference and policy implications

From the theoretical perspective the presented results are consistent with the argumentation of new institutional economics in the context of evolutionary research on the determinants of technological changes. Additionally, the formal quantitative methodology applied in the research can be complementary proposal to qualitative approach that dominates in the case of institutional framework.

From the policy perspective, the results of the research highlight the importance of institutional reforms in the European Union. The modifications of formal regulations that are up to the requirements of the KBE would improve the productivity of the European countries and the European economy as a whole. It is consisted with the discussion concerning Europe 2020 implementation (see Hobza and Mourre, 2010, Denis *et al.* 2005, Balcerzak 2015c, pp. 190-210). In the case of the “new” member states the institutional reforms are essential for increasing the speed of catching up with the “old” members. From the perspective of the common European market, they are important for keeping and eventually improving the European competitive position in the global economy.

4. Conclusions

The article concentrates on the issue of evaluation of TFP changes in the EU countries in the years 2000-2010. Special attention was given here to the influence of quality of institutions on the TFP. In the first part TFP at the national level for EU was evaluated. Then, a method for quantifying the quality of institutions in the context of the KBE was proposed. From the institutional perspective the presented approach was rooted in the transaction cost theory. From the numerical point of view it was based on the Hellwig's concept of pattern of economic development. Referring to the research on the determinants of productivity changes in OECD countries the authors proposed four segments of national institutional system that are important from the perspective of utilization of potential of technological changes and the KBE as a whole. Based on these four segments the total measure of development for quality of institutions in the EU countries was calculated.

Then, the influence of quality of institutions for the KBE on the TFP in the EU countries with the application of panel model was estimated. The results of the econometric analysis enabled to verify both hypotheses of the article, the first one concerning the positive influence of the quality of institutions on TFP in the EU countries and the second one, which pointed to

especially high potential in the case of the “new” member states in improving their TFP under the condition of effective institutional reforms.
