Promise not Fulfilled: FinTech, Data Privacy, and the GDPR

Abstract

This article analyzes how the General Data Protection Regulation (GDPR) has affected the privacy practices of FinTech firms. We study the content of 308 privacy statements respectively before and after the GDPR became binding. Using textual analysis methods, we find that the readability of the privacy statements has decreased. The texts of privacy statements have become longer and use more standardized language, resulting in worse user comprehension. This calls into question whether the GDPR has achieved its original goal—the protection of natural persons regarding the processing of personal data. We also analyze the content of privacy statements and link it to company- and industry-specific determinants. Before the GDPR became binding, more external investors and a higher legal capital were related to a higher quantity of data processed and more transparency, but not thereafter. Finally, we document mimicking behavior among industry peers with regard to the data processed and transparency.

JEL-Codes: K200, L810.

Keywords: data privacy, FinTech, General Data Protection Regulation, privacy statement, textual analysis, financial technology.

1. Introduction

Data have become a critical resource for many business models as a result of digitalization and globalization. Individuals disclose personal information intentionally and unintentionally over the Internet and when using their smartphones (Lindgreen, 2018; World Bank, 2021). Because of the international location of servers and cloud-computing services, the processing of data often takes place under different jurisdictions and does not stop at national borders. On May 25, 2018, the General Data Protection Regulation (GDPR) became binding in the European Economic Area (EEA)² to address the increasing challenges of data security and privacy. The GDPR extends its territorial reach even outside the EEA if European data are involved. The financial sector and, in particular, the recently emerging Financial Technology (FinTech) industry process large amounts of sensitive data. Payment data, for example, can entail information about racial or ethnic origin, political opinions, religious beliefs, trade-union membership, health or sex life. The different FinTech business models, which frequently rely on artificial intelligence, big data, and cloud computing, thus represent an important and relevant industry to examine the impact of the GDPR on data privacy practices.

Companies are not required by law to have a privacy statement; however, they often comply with the requirement to inform their users (art. 13-15 GDPR), by publishing such statements, about the personal data they process. Therefore, privacy statements serve as research objects for many studies that analyze privacy. For example, Ramadorai et al. (2021) study a signalling model of firms engaging in data extraction. They analyze a sample of 4,078 privacy statements of U.S. firms and find significant differences in accessibility, length, readability and quality between and within the same industries. Large companies with a medium level of technical sophistication appear to use more legally secure privacy statements and are more likely to share user data with third parties. Other studies analyze the effect of privacy regulation by comparing privacy-statement versions before and after the GDPR became binding. Becher and Benoliel (2021), for instance, focus on the “clear and plain language” requirement in the GDPR (art. 12 GDPR). By analyzing the readability of 216 privacy statements of the most popu-

²Thus, it applies in the European Union (EU) and the three countries of the European Free Trade Association.

lar websites in the United Kingdom and Ireland after the GDPR became binding, they conclude that privacy statements are hardly readable. For a small sub-sample of 24 privacy statements before and after the GDPR became binding, they document a small improvement in readability. In another study, Degeling et al. (2019) periodically examine, from December 2017 to October 2018, the 500 most popular websites of all EU member states, gathering a final sample of 6,579 privacy statements, and find that the number of sites with privacy statements increased after the GDPR became binding. When focusing on cookie consent libraries, they conclude that most cookies do not fulfill the legal requirements. Linden et al. (2020) study 6,278 privacy statements inside and outside the EU. They underline that the GDPR was a main driver of textual adjustments and that many privacy statements are not yet fully compliant regarding disclosure and transparency. This article extends the previous research by focusing on the FinTech industry, which is characterized by the presence of many startup companies and tends to process highly sensitive data. To address the peculiarities of the companies within this industry and the data they process, we link the analysis of privacy statements to company- and industry-specific factors.

A central goal of the GDPR is that communication to data subjects about the processing of data occur in a concise, transparent, intelligible and easily accessible form, using clear and plain language (art. 12 GDPR). In this paper, we analyze 308 privacy statements published by German FinTech firms before and after the GDPR became binding. We analyze readability, standardization, whether company- and industry-specific factors affect the quantity of data processed, and the transparency of privacy statements. We perform textual analysis on the privacy statements and provide evidence that their readability has worsened since the GDPR became binding. Specifically, the texts have become longer and more time-consuming to read. In a next step, we find an increase in the use of standardized text. Further, we study the quantity of data processed as stated in the privacy statements and the related level of transparency. We study whether company-specific factors such as the number of external investors and the existence of bank cooperation predict privacy practices respectively before and after the GDPR became binding. Finally, peer pressure and industry standards might induce mimicking behaviour. We find that *ex-ante* industry-wide privacy practices positively influence companies' privacy practices after the GDPR became binding. Our results remain robust when excluding more mature FinTechs, when extending the analysis to privacy statements published in English lan-

guage and when using alternative model specifications.

The rest of this article is organized as follows. Section 2 describes the relevant provisions of the GDPR, the recent literature, and develops the hypotheses that will be tested. Section 3 outlines the data and method. Section 4 presents our results. Section 5 provides robustness checks, and Section 6 concludes.

2. Theoretical background

2.1. *The GDPR*

The European Parliament passed the GDPR on April 14, 2016. After a transition period, the regulation became binding on May 25, 2018. The regulation is intended to harmonise privacy legislation in the EU. According to its territorial scope (art. 3 GDPR), data of EU citizens are subject to the regulation, independent of whether the data are processed inside or outside the EU. After the GDPR became binding, many jurisdictions outside the EU adopted privacy regulations with a scope and provisions similar to those in the GDPR.³ The GDPR distinguishes between four main actors in the field of privacy: the data subject, who is a natural person and whose personal data are processed; the data controller, as the entity offering products or services for which the data are needed; the data processor, supporting the data controller to process the data; and third parties that might process data not directly related to the product or service provision (e.g., companies evaluating a user's credit-worthiness) (Linden et al., 2020). To give the GDPR bite, fines of up to 4% of a company's yearly global revenue or 20 million euros can be imposed in cases of non-compliance (art. 83 GDPR).

2.2. *Literature and Hypotheses*

The theoretical foundation of this study is built on the economics of privacy literature investigating economic trade-offs that reveal people's considerations in terms of privacy.⁴ The economics of privacy literature is em-

³Specific examples of privacy regulations similar to the GDPR are the California Consumer Privacy Act of 2018, the Personal Data Protection Act 2019 in Thailand, the Brazilian General Data Protection Law of 2020, the Swiss Federal Act on Data Protection of 2020, and the Chinese Personal Information Protection Law of 2021.

⁴For a literature review on the economics of privacy, see Acquisti et al. (2016).

bedded in the broader context of information economics (Posner, 1981) and is substantially affected by the advances in digital information technology.

The GDPR as a new privacy regulation affects nearly every area of life where natural persons claim a service or product with or in exchange for personal data. Therefore, the encompassing consequences and the economic impact of the GDPR are quantified in several studies and highlight a decrease in web traffic, page views and revenue generated as a result of the consent requirement on the part of the data subject (art. 7 GDPR) or limitations in marketing channels (Aridor et al., 2020; Goldberg et al., 2021).

Privacy statements are the essential source of information about how companies put privacy into practice and process personal data. These statements are the standard way to promote transparency to users (Martin et al., 2017) and to balance the equity of power between data subjects and data processors (Acquisti et al., 2015). Therefore, privacy statements are often used in the literature to analyze privacy-related aspects of companies as outlined in the Introduction. Computer and information science scholars have developed tools that help researchers analyze privacy statements on a large scale (Contissa et al., 2018; Harkous et al., 2018; Tesfay et al., 2018). Contissa et al. (2018), for example, apply their tool to the privacy statements of large-platform and BigTech companies as an exploratory inquiry and conclude that none fully comply with the GDPR, as the formulations are partially unclear, potentially illegal or insufficiently informative.

Privacy and security aspects of FinTech companies have been studied in a variety of contexts. Stewart and Jürjens (2018) survey the German population regarding FinTech adoption and identify data security, consumer trust and user-design interface as the most important determinants. Gai et al. (2017) provide a theoretical construct for future FinTech industry development to ensure sound security mechanisms based on observed security and privacy concerns and their solutions. Other studies emphasize the specificity and importance of the data processed by FinTechs. Ingram Bogusz (2018) describes and distinguishes the data that FinTechs process between *content data*, directly related to the identification of a person, and *metadata*, usually left unintentionally by users but useful for the data processor. Berg et al. (2020) demonstrate the large opportunities to use data collected during 250,000 purchases on a German e-commerce website. Among other things, such data has significant explanatory power to determine creditworthiness. Dorfleitner and Hornuf (2019) provide a descriptive analysis of privacy statements of German FinTechs before and after the GDPR became binding to

derive policy recommendations. However, apart from Dorfleitner and Hornuf (2019), the preliminary research does not analyze the privacy statements of FinTech companies specifically regarding privacy regulation and the GDPR. We further link the analysis of the FinTechs privacy statements to company- and industry-specific factors in order to account for the diversity and specificity of business models within the industry.

Privacy practices can have many aspects. In line with the provisions of the GDPR, we investigate the theoretical concepts of readability, standardization, quantity of data processed, and transparency in the subsequent analysis.

Readability. The GDPR requires that information and communication be transmitted to users in clear and plain language (art. 7, 12 GDPR, rec. 42, 58 GDPR). This objective corresponds to the linguistic concept of readability, i.e. the reader's ease with and ability to understand a text. Apart from the legislative requirements of the GDPR, companies also have an economic incentive to provide readable privacy statements, which in turn can increase user trust in their business conduct (Ermakova et al., 2014) and thereby create a competitive advantage (Zhang et al., 2020). While these arguments seem to suggest that companies should have increased the readability of their privacy statements after the GDPR became binding, there are also severe counterarguments. Many users do not read mandatory disclosures such as privacy statements (Omri and Schneider, 2014), even for products and services they use daily (Strahilevitz and Kugler, 2016). Firms provided their users, often within a very short time frame, updated privacy statements after the GDPR became binding (Becher and Benoliel, 2021). It appears unlikely that such a large number of new privacy statements has triggered additional engagement with these texts by data subjects. Indeed, several studies state that privacy statements are difficult and time-consuming to read and often require an understanding of complex legal or technical vocabulary (Fabian et al., 2017; Lewis et al., 2008; Sunyaev et al., 2015). Second, and in line with this observation, Earp et al. (2005) and Fernback and Papacharissi (2007) find that privacy statements often aim to protect companies from contingent lawsuits rather than address the privacy needs of data subjects. Thus, while firms know that their customers tend to ignore privacy statements, especially if they are technical to read, they may have emphasized their own interests with respect to avoiding lawsuits when updating these statements with respect to the GDPR. Indeed, as long as there is no need for companies to fear

that the requirement of clear and plain language will become the subject of legal proceedings, they have few incentives to improve the readability of their privacy statements.

This theoretical argumentation is supported by empirical evidence. Two years after the GDPR became binding, the penalties imposed on companies remain relatively low, and none traces back to the clear and plain language requirement (Wolff and Atallah, 2021). Becher and Benoliel (2021) analyze the readability of 216 privacy statements of the most popular websites in the United Kingdom and Ireland and find that many of the pre-GDPR statements are barely readable and that this has only slightly improved for the analyzed small sample of 24 privacy statements since the GDPR became binding. Linden et al. (2020) study 6,278 privacy statements before and after the GDPR became binding using different text metrics like syllables, word count or passive voice and state that the policies became significantly longer but that there was no change in sentence structure.

Summarizing this reasoning, we expect that companies may not have significantly improved the readability of their privacy statements after the GDPR became binding in May 2018.

Hypothesis 1: *The readability of privacy statements has not improved since the GDPR became binding.*

Standardization. The standardization of legal text is often deemed uninformative for the reader and is therefore referred to as *boilerplate* in academic literature. Boilerplate language is characterized by very similar uses of language and wording across legal documents from different issuers (Peacock et al., 2019) and little company-specific information (Brown and Tucker, 2011). For a user, boilerplate text requires much effort to read, and details might appear to be irrelevant (Bakos et al., 2014).

Boilerplate language in legal text brings cost advantages for companies. First, the costs of adopting the specific legal requirements such as the GDPR are lower for all market participants. Second, reduced legal uncertainty due to the use of established and proven text passages, which have yet to cause legal violations, promises fewer future penalties (Kahan and Klausner, 1997). For many companies, the GDPR provided an incentive to intensively address and spend resources on data privacy compliance (Martin et al., 2019). During the period of transition to the GDPR, organizations looked for external information and support regarding the implementation of its legal requirements. Companies often rely on compliance assessment tools to audit their

business processes for legal compliance (Agarwal et al., 2018; Biasiotti et al., 2008). In the related literature of requirements engineering, boilerplate language is often proposed to reduce text ambiguities (Arora et al., 2014). For example, Agarwal et al. (2018) provide a tool specifically designed for assessing GDPR compliance, including one process step that allows the user to incorporate boilerplate language. Other sources of information are websites or online policy generators, which deliver guidance on implementing and interpreting the GDPR or even templates for generating privacy statements.⁵ The mentioned advantages of applying boilerplate language as well as the examples of assistance to GDPR compliance underpin that we can expect an increase in boilerplate language in the privacy statements since the GDPR became binding.

Hypothesis 2: *The standardization of privacy statements has increased since the GDPR became binding.*

Quantity of data processed and transparency. For a comprehensive analysis of the FinTechs' privacy practices beyond readability and standardization, we investigate the content of the privacy statements. While the mere quantity of data processed is important in a first step, we also consider the level of transparency.

At the core of the GDPR are principles related to the processing of personal data (art. 5 GDPR), in particular the articles related to lawful, fair and transparent data processing as well as data minimization (art. 5 (1a, c), rec. 39 GDPR). An increase in transparency ensures that consumers provide better-informed consent with respect to the data processed (art. 4, 11 GDPR) (Betzing et al., 2020). An imprecise statement about which and how much personal data are processed violates the provisions of the GDPR, which in turn can result in high penalties. Thus, with regard to the expected costs, an accurate disclosure about which data are processed outweighs the general principle of data minimization. However, the major change of the GDPR introduced compared with the previous privacy legislation in Germany is the potential for high penalties (Martin et al., 2019). This fact represents an incentive for companies to rework their privacy statements, to be precise about

⁵A template for privacy statements funded within the Horizon 2020 Framework Program of the European Union is provided at <https://gdpr.eu/privacy-notice/>, last access: 31 August 2021.

the quantity of data processed and to enhance transparency after the GDPR became binding.

Regarding the behavior of data subjects, we apply the theoretical considerations of the privacy calculus model. Data disclosure is the result of a consumer’s individual cost-benefit analysis, referred to as a privacy calculus, according to which costs and benefits of disclosing personal data are weighed against each other (Dinev and Hart, 2006). The potential risks of data disclosure are difficult to assess and will only appear in the future, which is why benefits often outweigh costs in the short run (Acquisti, 2004). Data subjects must consent to the privacy statements that are written by companies if they are to receive immediate gratification (O’Donoghue and Rabin, 2000) or, more concretely, to obtain a desired service or product (Aridor et al., 2020). The notion behind many business models is that customers actively forsake parts of their data privacy in exchange for goods and services (Mulder and Tudorica, 2019). Therefore, the data subject’s control over the data processed and transparency is limited, and companies have the upper hand.

Empirical studies evidence that it is beneficial and important for companies to ensure and enhance transparency. Li et al. (2019) show that transparency may enhance trust and reputation in a business’s activities. Martin et al. (2017) find that a higher level of transparency in the case of a data breach results in a lower negative stock-price reaction.

To summarize the argumentation, we expect an increase not only in the quantity of data processed but also in transparency as companies fulfill the legal requirements of the GDPR and avoid potentially high penalties while benefiting economically.

Hypothesis 3a: *The quantity of data processed has increased since the GDPR became binding.*

Hypothesis 3b: *The level of transparency has increased since the GDPR became binding.*

Determinants of the quantity of data processed and transparency. Young companies, such as most FinTechs, prioritize the core business instead of privacy compliance when launching a seminal business. Moreover, founders are rarely experts in privacy or law. Nevertheless, when starting business operations, FinTechs inevitably process personal data and need to act in order to protect privacy sufficiently (Miller and Tucker, 2009) and to comply

with current privacy regulation. Therefore, the question arises whether some FinTechs meet the legal requirements better than others. External investors contribute knowledge and experience to build a proper and future-oriented company. The advanced knowledge of external investors is based on experience in legal compliance and privacy with corresponding business contacts and cooperations (Hsu, 2006). The more external investors are involved in an investment, the more likely it is to succeed as a business because of the access to external knowledge (De Clercq and Dimov, 2008). We hypothesize that having a greater number of investors with different education, experience and background knowledge help achieve privacy compliance.

Hypothesis 4a: *External investors increase the quantity of data processed and transparency.*

Another important group of stakeholders for FinTechs are the banks they may collaborate with. Within such cooperation, FinTechs receive access to financial resources, infrastructure, customers, security reputation (Drasch et al., 2018), a banking license and legal support to comply with regulation (Hornuf et al., 2020). Moreover, banks have a strong incentive to collaborate with FinTechs in order to boost their digital transformation, which might result in more data being shared. Banks also have long-term experience managing personal data and handling data in compliant way. Banks can transfer this knowledge to FinTechs, especially if they cooperate. We therefore expect that cooperation with a bank has a positive effect on compliance with privacy regulation.

Hypothesis 4b: *Cooperations with banks increase the quantity of data processed and transparency.*

Mimicking behavior. Prior studies evidence that companies tend to mimic the behavior of other companies in the same industry, including for stock repurchase decisions (Cudd et al., 2006), target amounts in crowdfunding (Cumming et al., 2020) or tax avoidance (Kubick et al., 2015). An industry-centric perspective with regard to privacy appears to be reasonable; as Martin et al. (2017) show, when a specific entity experiences a privacy breach, the firm performance of companies in the same segment is also affected. In our study, FinTechs operating in the same sub-segment and thus having corresponding business models should also have similar data processing practices (Hartmann et al., 2016). Consequently, there is an incentive to adopt an immediate peer’s privacy statement. Mimicking an industry peer’s behavior in

the field of privacy is fairly easy, as the privacy statements can be accessed on the corresponding website with just a few clicks. Firms in the same segment can expect to incur similar fines and penalties in cases of non-compliance (Hajduk, 2021). Expert interviews in the context of the GDPR reveal that start-up executives have concerns that their industry peers could report their possible violations to the data protection authorities (Martin et al., 2019). Mimicking industry peers and adopting similar privacy practices prevents companies from experiencing such adversity.

We therefore expect that the industry-specific design of privacy practices stated in privacy statements has a positive influence on a single company’s quantity of processed data and transparency.

Hypothesis 5: *Mimicking behavior has a positive influence on the company-specific quantity of data processed and transparency.*

3. Data and Method

3.1. Data

Our sample consists of companies operating in financial technology in Germany.⁶ Data collection before the GDPR became binding, on 25 May 2018, took place between 15 October 2017 and 20 December 2017. Data collection after the GDPR became binding occurred between 15 August 2018 and 31 October 2018. The sample is further split into 276 companies with privacy statements in German, analyzed in Section 4, and 32 companies with privacy statements in English, examined in Section 5, as the textual processing of different languages requires a separate treatment because of semantic and morphological differences.

3.2. Variables

To test Hypothesis 1, we use the readability measures *SMOG German*, *Wiener Sachtext* and, alternatively, *No. words*. For a test of Hypothesis 2 to examine standardization, we calculate the similarity and distance metrics *Cosine similarity*, *Jaccard similarity*, *Euclidean distance* and *Manhattan*

⁶Study data are kindly provided by Dorfleitner and Hornuf (2019). We reduced the original data set to 308 companies because of the non-availability of privacy statements, inconsistencies in company data and inactivity or insolvency during both data collection periods.

distance. We describe these text-based measures and their respective calculations in more detail in Section 3.3.

3.2.1. Variables of interest

To test Hypotheses 3a and 3b, 4a and 4b and 5, we construct a *data index* to account for the quantity of data processed and the *transparency index* for actions undertaken to ensure transparency. The underlying assumption of the index construction is that we assume that when a company does not concretely state the processing of specific data or certain data-processing practices, such processing does not occur. After the GDPR became binding, this assumption seems justified given the high potential penalties for misrepresentation.

The *data index* is a measure of the quantity of data processed by a company. The data processed ranges from general personal data (e.g. name, address) to metadata (e.g. IP address, social plugins) to special categories of personal data (e.g. health, religion). Table 1 provides the full list of data categories from which the *data index* is composed. For the variable *transparency index*, we aggregate variables representing different dimensions of transparent data-protection actions undertaken by the companies. Apart from vague formulations in art. 12 and rec. 58, 60, the GDPR does not explicitly define and specify transparency or how to ensure transparency. Therefore, we combine the potential transparency vulnerabilities of Mohan et al. (2019) and Müller et al. (2019) to define our considered dimensions of transparency. The *transparency index* represents the normalized sum over eight dummy variables such as *data* (whether a company states in detail which personal data they process), *purpose* (1 if a company states for what reason or purpose personal data are processed) and *storage* (1 if it states how long data are stored or when they are deleted). Table 1 lists in detail the composition of the *transparency index*.

- Insert Table 1 here -

As proposed by Wooldridge (2002, p. 661), we divide the indices *data index* and *transparency index* by the maximum achievable number of variables of which the respective index is composed to scale them between 0 and 1. We interpret a higher index value to mean respectively a higher quantity of data processed and more transparency.

3.2.2. Explanatory variables

To construct our explanatory and control variables, we collect detailed firm-specific variables, which we describe below with the data sources used. Accuracy of the data was validated using cross-checks with press releases, FinTech websites and other news and information online.

To test Hypothesis 4a, that a higher number of external investors positively influences the quantity of data processed and transparency, we include the variable *No. investors*, measured as the absolute number of external investment firms and individual investors who funded the company. This variable is already considered in other FinTech-related studies such as Cumming and Schwiendbacher (2018) and Hornuf et al. (2018b). We derive the variable from the BvD Dafne and Crunchbase database, which was also used in other academic papers, such as Bernstein et al. (2017) and Cumming et al. (2019).

To test Hypothesis 4b, we include the dummy variable *bankcooperation*, which equals 1 if the respective company has a cooperation with a bank and 0 otherwise. For data collection, we first searched all bank websites to find indications of bank–FinTech cooperation. In a second step, we checked for cooperation from the FinTech side.

To analyze mimicking behavior as outlined in Hypothesis 5, we follow the approach of Cudd et al. (2006), who use the industry average of a measure in the year preceding the focal period for mimicking behavior. We obtain the variables *mimic data index* and *mimic transparency index* by calculating the average of the indices *data index* and *transparency index* within the same FinTech sub-segment before the GDPR became binding according to the taxonomy of Dorfleitner et al. (2017).

3.2.3. Control variables

To consider unobserved heterogeneity, we use the following control variables. First, we control for firm location with the variable *city*, which can be a relevant geographic determinant. This variable indicates whether a company is located in a city with more than one million inhabitants. In metropolitan areas, more customers and sources for funding (Hornuf et al., 2020) as well as start-up incubators are within geographical reach and thus available to support a company’s development. Besides, more FinTechs are located in one place in metropolitan areas, which often leads to the establishment of entrepreneurial clusters (Porter, 1998). Competition within a cluster necessitates the creation of a competitive advantage (Tsai et al., 2011), which is

a quality signal of compliance with applicable privacy regulation. Gazel and Schvienbacher (2020) provide empirical evidence that location in a cluster reduces the risk of firm failure for FinTechs. We collected the data from the German company register.

Second, we consider the variable *legal capital*. This variable reflects the founder’s dedication and readiness to make a notable investment in the own venture at an early stage of development (Hornuf et al., 2021) and which can be interpreted as a quality signal of motivation and future success of business operations. In Germany, for the most common legal form of a limited liability company (the so-called *GmbH*), one needs to raise legal capital of at least 12,500 EUR at the time of incorporation. The dummy variable equals 1 if the minimum capital requirement of the underlying legal form amounts to more than 1 EUR and 0 otherwise. We derived this information from the German company register and imprints of the FinTech websites.

Third, we include number of *employees* as a proxy for FinTech companies’ human capital and size (Hornuf et al., 2018a). *Employees* is a rank variable ranging from 1 to 5 and representing number of employees: 1-10, 11-50, 51-100, 101-1000 and above 1000. A larger number of employees usually means a more diversified team in terms of members’ abilities and skills, resulting in venture success (Duchesneau and Gartner, 1990), which might also translate to compliance and legal aspects. For privacy-related aspects, Ramadorai et al. (2021) outline that larger firms tend to extract more data. Therefore, we proxy for firm size and human capital strength using the number of employees. We derived the data from BvD Dafne and complemented them with data from the Crunchbase database as well as LinkedIn entries.

Fourth, we control for the age of the FinTech company during the particular data-collection period since its year of incorporation with the variable *firm age*. This variable serves as a proxy for a FinTech’s stage of business (Hornuf et al., 2021). We assume that established companies pay more attention to privacy aspects because they have more experience and available resources. Bakos et al. (2014) find for contracts in boilerplate language that consumers have more confidence in larger and older companies because they seem more credible and fair. We derive the year of incorporation from the German company register and respectively calculate it as the difference of the data collection period before and after the GDPR became binding.

We further include *industry dummies* to account for the diversity of business models. Our industry classification follows the FinTech taxonomy of Dorfleitner et al. (2017) with the segments and sub-segments financing

(donation-based crowdfunding, reward-based crowdfunding, crowdinvesting, crowdlending, credit and factoring), asset management (social trading, robo-advice, personal financial management, investment and banking), payments (alternative payment methods, blockchain and cryptocurrencies, other payment FinTechs) and other FinTechs (insurance, search engines and comparison websites, technology IT and infrastructure, other FinTechs). The categorization is based on FinTechs' business models in accordance with the functions and business processes of traditional banks. The business model provides first indications about the data processing of a specific FinTech because in a digitized industry, data are often at the core of the business model.

The variables *employees*, *legal capital*, *bankcooperation* and *city* are time-invariant. We collected the remaining variables in this paper before and after the GDPR became binding.

3.3. Methods

3.3.1. Textual analysis: preprocessing

We prepare the texts of the privacy statements using standard methods of text mining including cleaning for white spaces, numbers, punctuation and other symbols. For the standardization analysis, we further remove capitalization and apply stemming to reduce words to their root in order to consider different grammatical forms of the same word-family. Because stop words such as articles, conjunctions and frequently used prepositions lack additional meaning, we delete stop words. Subsequently, we break the texts down into tokens that represent individual words and count their frequency within each text separately for both data-collection periods.

3.3.2. Readability

The GDPR lacks a common meaning of “clear and plain language” (art. 12 (1) GDPR) with which to evaluate the comprehensibility of privacy statements. Readability is defined as the ease of understanding a text and is usually measured using formulas based on sentence length, syllables and word complexity. The most commonly used readability measures in academic literature are the Flesch reading ease score (Flesch, 1948) and the Gunning Fog Index (Gunning, 1952), both corresponding to the number of formal years of education required to comprehend a text. We investigate companies operating in Germany and because the privacy statements are often written in

German, we address the variety of morphological and semantic richness by using metrics for or adapted to German.

First, we apply the Neue Wiener Sachtext formula by Bamberger and Vanecek (1984) using the formula

$$nWS = 0.1935 \cdot \frac{n_{wsy \geq 3}}{n_w} + 0.1672 \cdot ASL + 0.1297 \cdot \frac{n_{wchar \geq 6}}{n_w} - 0.0327 \cdot \frac{n_{wsy=1}}{n_w} - 0.875$$

where $n_{wsy \geq 3}$ is the number of words with three syllables or more, ASL is the average sentence length (number of words / number of sentences), $n_{wchar \geq 6}$ is the number of words with 6 characters or more and $n_{wsy=1}$ is the number of words of one syllable.

Second, we calculate the simplified SMOG metric of McLaughlin (1969) adapted to the peculiarities of the German language as

$$SMOG \text{ German} = \sqrt{Nw_{min3sy} \cdot \frac{30}{n_{st}} - 2}$$

where Nw_{min3sy} is the number of words with a minimum of three syllables and n_{st} is the number of sentences.⁷ While these formulas for determining readability are frequently used in the literature (Loughran and McDonald, 2016; Ramadorai et al., 2021), they are nevertheless often criticized (Loughran and McDonald, 2014). Regarding privacy statements, Singh et al. (2011) state that the measures take into account sentence complexity and word choice but no aspects that determine comprehension. To address these points of criticism, we additionally consider the variable *No. words*, defined as the logarithm of the total number of words in the privacy statements. We consider the variable as an alternative measure of the understandability and complexity of a text reflected in the time required to read the whole text.

3.3.3. Standardization

To test Hypothesis 2, we quantify the extent to which the texts of privacy statements are standardized by calculating common measures of text similarity and distance for dissimilarity. We apply the vector space model (VSM) of Salton et al. (1975) to convert texts into term frequency vectors, which enables us to perform algebraic calculations. The accounting and finance

⁷The formula of the simplified SMOG metric for the English language is $SMOG = \sqrt{Nw_{min3sy} \cdot \frac{30}{n_{st}} + 3}$.

literature often applies Cosine or Jaccard similarity to account for similarity (Cohen et al., 2020; Peterson et al., 2015).⁸

As a first similarity measure, we calculate the *Cosine similarity*. Because of the vector representation of the texts, we can calculate the cosine of the included angle. The *Cosine similarity* between two documents is defined as the scalar product of the two term frequency vectors divided by the product of their Euclidean norms. The values range from 0 to 1 because term-frequency vectors of texts cannot be negative. A main property of the *Cosine similarity* is that it does not consider text length. A value close to 1 indicates the presence of pure boilerplate language. The second similarity measure we calculate is *Jaccard similarity*, defined as the quotient of the size of the intersection and the size of the corresponding union of two term-frequency representations. In contrast to *Cosine similarity*, for the *Jaccard similarity* each word occurs only once in the sample, and its frequency is not accounted for. For privacy statements, Ramadorai et al. (2021) use Cosine similarity to analyze industry-specific boilerplate, whereas Kaur et al. (2018) employ Jaccard similarity to measure keyword similarity. Besides the similarity measures, we calculate the two distance metrics *Euclidean distance* and *Manhattan distance*. *Euclidean distance* is the shortest distance between the two document vectors with the corresponding term weights. In contrast to *Euclidean distance*, *Manhattan distance* is the absolute distance between the two vectors. Unlike for the similarity measures, values of distance metrics close to 1 indicate no correspondence between the analyzed texts.

We calculate all the aforementioned similarity and distance measures pairwise for the privacy statement texts D_1 and D_2 of two different companies within one data-collection period. In the next step, to obtain one average similarity or distance-measure value for one company before and after the GDPR became binding, we calculate our similarity and distance measures in relation to the average privacy statement per period, analogous to the “centroid vector [or] the average policy” of Ramadorai et al. (2021), as

$$\bar{D} = \frac{\sum_{n=1}^N D_n}{N} \quad (1)$$

where \bar{D} is the average value per year, $\sum D_n$ the sum of the similarity respective distance of one FinTech’s document in relation to every other document,

⁸For illustrative examples of Cosine and Jaccard similarity, see Cohen et al. (2020).

and N the number of companies.

3.3.4. Empirical Approach

To test our Hypotheses 1, 2, 3a and 3b, we use a two-sided paired t-test to examine whether the means of readability, standardization, quantity of data processed, and transparency are significantly different for the periods before and after the GDPR became binding.

We test Hypotheses 4 and 5 in a multivariate setting. Because our dependent variables are fractional indices in the interval between 0 and 1, we estimate fractional probit regressions using quasi-maximum likelihood (Papke and Wooldridge, 1996).

We further explore in Hypothesis 4 determinants of the *data index* and *transparency index* in separate models before and after the GDPR became binding. To compare the obtained regression coefficients of non-linear models for the same sample of companies at two different points in time, we further conduct seemingly unrelated estimations (Zellner, 1962). Then, we perform Wald chi-square tests to test whether the coefficients differ across our analyzed periods. The validity of the tests is ensured by the previously performed estimation based on the stacking method with respect to the appropriate covariance matrix of the estimators for the standard errors (Weesie, 1999) and was formerly successfully applied by Mac an Bhaird and Lucey (2010) and Laursen and Salter (2014).

4. Results

4.1. Sample

Figure 1 shows the graphical distribution of the companies in their industries following the detailed FinTech taxonomy of Dorfleitner et al. (2017). Table 2 provides summary statistics for all our variables. Most of the companies in the sample operate in the crowdinvesting and alternative payments, insurance respective IT, technology and infrastructure sub-segments. Crowdinvesting can be a data-intensive sub-segment (Ahlers et al., 2015), whereas payment providers receive manifold payment data that can entail almost all possible information about a person. Moreover, insurance companies typically process health data, which are special categories of personal data (art. 9). The descriptive statistics of *bankcooperation* indicate that, on average, 25.4% of FinTechs in our sample maintain a cooperation with a bank. The

median of *No. investors* is 0, which indicates that less than half the companies in the sample have received external funds. The mean and median values of *employees*, around 2, indicate that most of our FinTechs are small companies employing 11 to 50 people. The variable *city* indicates that, on average, 48.6% of the analyzed FinTechs are located in a large city.

- *Insert Figure 1 here* -

- *Insert Table 2 here* -

4.1.1. Readability

The mean and median in combination with the quantiles of the readability metrics *Wiener Sachtext* and *SMOG German* increase slightly, which indicates that the readability of the privacy statements worsened after the GDPR became binding. In Table 3, two t-tests indicate a significant difference in means for both metrics (paired t-tests, $t = 2.569$ and $p < 0.05$, $t = 6.010$ and $p < 0.01$). The alternative readability proxy *No. words* shows a clear increase in any summary statistic, which indicates a worsening in readability and is confirmed by a t-test on differences in means (paired t-test, $t = 15.017$, $p < 0.01$).

- *Insert Table 3 here* -

The cumulative distribution functions of all our variables considering readability are illustrated in Figure 2. A shift of the graph to the right indicates a worsening in readability from before (black) to after (grey) the GDPR became binding, which is evident for all our measures. These results are contrary to the GDPR's objective of clear and plain language. A discussion of the result for *Wiener Sachtext* and *SMOG German* requires a closer look at the method. Both metrics are mainly calculated based on word complexity and sentence length. In particular, word complexity is a critical issue for technical termini, which accompanies privacy-related legalese. Because the information content and quality regarding advanced technological topics can suffer from simpler language (Wachter, 2018), it is not surprising that in the FinTech domain a more complex language has recently been used. Our results for *No. words* are in line with Linden et al. (2020), who find in their before and after the GDPR comparison an increase in text length but no changes in sentence structure. Thus, our evidence supports Hypothesis 1.

- *Insert Figure 2 here* -

4.1.2. Standardization

In this section, we test Hypothesis 2 on the increase of boilerplate language after the GDPR became binding. The similarity measures *Cosine similarity* and *Jaccard similarity* reveal a clear increase in mean and median. Both measures indicate an increase in boilerplate language, which is confirmed by a t-test for differences in means at conventional levels (paired t-tests, $t = 8.606$ and $p < 0.01$, $t = 6.880$ and $p < 0.01$). Consistent with the similarity metrics, we identify for the distance metrics *Euclidean distance* and *Manhattan distance* a decrease in means and medians, indicating an increase in the use of boilerplate language. The means are statistically significantly different before and after the GDPR became binding (paired t-tests, $t = -12.530$ and $p < 0.01$, $t = -7.074$ and $p < 0.01$). The standard deviation for all measures remains almost the same for both sample periods. Regarding all of our similarity and distance metrics, the first and third quantiles are far from the minima or maxima, illustrating that although some outliers exist, there is a tendency towards the mean and the median. In Figure 3, the cumulative distribution function of the similarity and distance measures illustrates a shift to more similar and therefore standardized language from before (grey) compared with after (black) the GDPR became binding.

- Insert Figure 3 here -

In sum, we find an increase in privacy statements' use of boilerplate language after the GDPR became binding. Companies appear to have chosen the path towards legal-safeguarding boilerplate policies to the detriment of their users. Overall, Hypothesis 2 receives support.

4.1.3. Quantity of data processed and transparency

We now analyze the content of the privacy statements.⁹ For the *data index*, we find an increase in the mean and median from before to after the GDPR became binding, which illustrates that companies state more often in their privacy statements post-GDPR that they process specific data. The difference is statistically significant in a t-test (paired t-test, $t = 5.940$, $p < 0.01$). Thus, we find supportive evidence for Hypothesis 3a. A closer look at

⁹For detailed summary statistics of our disaggregated indices, we refer readers to Tables 14 and 15 in the Appendix.

all summary statistics emphasizes large divergences in the quantity of data processed between the individual companies. The *data index* minimum of 0 indicates that some firms do not state that they process any data. The range of the actual maximum value before and after the GDPR became binding indicates that even companies that process a lot of data are far from the maximum theoretical index value of 1.

For the *transparency index*, we find a small decrease in the mean and median. This finding suggests that, contrary to our Hypothesis 3b, companies' privacy practices have not improved in terms of transparency since the GDPR became binding. Note that there are companies in both periods reaching a maximum value of 0.875 for the *transparency index*, which indicates a high level of transparency. After performing a t-test on the mean, we find no statistically significant difference (paired t-test, $t = -0.940$, $p > 0.05$). Thus, we find no empirical support for Hypothesis 3b, that transparency has increased since the GDPR became binding. In contrast to our results, Linden et al. (2020) use different but closely related transparency measures and conclude that transparency has improved since the GDPR became binding but that privacy statements are far from fully transparent.

When considering the results of both indices, we conclude that since the GDPR became binding, FinTechs state that they process more data although they have not made efforts to enhance the transparency of privacy practices. Further, we identify large differences between individual companies. A possible explanation is that the FinTech industry as a whole is highly diverse and that the different business models require different intensities of data processing. For example, crowdinvesting platforms process a lot of data. The projects and initiator data need to be assessed in detail before the funding. During the funding process, disclosure of more information about the project and the initiators has been identified as a success factor (Ahlers et al., 2015).

4.1.4. Determinants of the quantity of data processed and transparency

Table 4 shows the results for Hypotheses 4a and 4b on the effect of the number of investors and the existence of a bank cooperation on the quantity of data processed and transparency.

- Insert Table 4 here -

We find that before the GDPR became binding, the coefficient of *No. investors* is positive and significant at the 5% level for both indices, where a one-standard-deviation increase in *No. investors* is associated with a 55.9%

increase in the *data index* in model (1) and a 41.2% increase in *transparency* in model (3). However, the effect and significance of the variable disappear for the period after the GDPR became binding in models (2) and (4). Before the GDPR became binding, the number of external investors had a positive effect on data-privacy compliance because it was positively related to the quantity of data processed and to transparency. Our results for *No. investors* provide partial support for Hypothesis 4a.

Further, none of our regression models yield a significant effect of *bankcooperation* on quantity of data processed or on transparency. Because of missing significances, we cannot provide further evidence for how external investors or cooperating banks influenced the implementation of the GDPR by FinTechs. Regarding *bankcooperation*, we find no empirical support for Hypothesis 4b.

The control variable *legal capital* has a significant positive influence on both indices for all models, which indicates that founders who invested more legal capital are also more dedicated to their business in terms of data privacy compliance. Wald tests for differences in coefficients before and after the GDPR became binding only show a significant difference for legal capital as a determinant of the *transparency index*. The coefficients for the *transparency index* are significantly different and lower after the GDPR (Wald chi-square test, $\chi^2 = 4.740$, $p < 0.05$). Thus, the effect of *legal capital* on transparency is stronger before the GDPR. This may be because before the GDPR became binding, only highly dedicated founders invested time in privacy compliance, whereas the GDPR made this issue the focus of every company. We consider variance inflation factors (VIF), reported in Table 8 in the Appendix, and find no indications of multicollinearity for any of our model specifications.

4.1.5. Mimicking behavior

The results for Hypothesis 5, which considers mimicking behavior regarding data privacy compliance among industry peers, are reported in Table 5.

- Insert Table 5 here -

In Table 5 model (1), we find a positive significant effect of the *mimic data index* on the 1% significance level, in which a one-standard-deviation increase in *mimic data index* is associated with a 58.6% increase in the *data index* relative to the average. In model (2), we find a highly significant impact of the *mimic transparency index* on the *transparency index*, in which a one-standard-deviation increase in the explanatory variables leads to a 75.27%

increase in the dependent variable relative to the average. The results indicate a strong mimicking behaviour among industry peers in terms of data privacy compliance, because a higher industry average for both indices before the GDPR became binding accompanies more data processed and greater transparency for a specific company.¹⁰ Thus, the conjecture that FinTechs mimic the privacy statements of their industry peers is supported by our evidence. As for our control variables, we find a weak statistically positive effect for *legal capital* for both indices. In sum, we find supportive evidence for Hypothesis 5 on mimicking behavior.

5. Robustness

Finally, we perform robustness checks and estimate alternative specifications to test the validity of our results.

5.1. Analysis of privacy statements in English

In the above analysis, we do not consider 32 privacy statements in English. In Table 9 in the Appendix, we report summary statistics for our English text-feature analysis. In contrast to our results for the statements in German, we find the readability measures for English statements to decrease in mean and median, indicating improved readability. However, this decrease in mean is not statistically significant. The *No. words* representing text length significantly increased after the GDPR became binding, similar to the German privacy statements. Our similarity and distance metrics do not show a consistent significant tendency. We refrain from further analyzing the English sample in the multivariate context. Because of the small sample size, mimicking behavior for the English sample cannot statistically be analyzed in the same way that we calculate the indices based on the industry-level averages of 16 industries for the remaining 32 companies. Consequently, considering only German privacy statements does not bias our results for the text-feature analysis.

¹⁰In unreported analysis, we estimate the same model using a mimicking variable based on segment-level averages of finance, asset management, payments and other FinTechs (n=4). Interestingly, we find for that specification no statistically significant coefficients and thus conclude that the less detailed categorization fails to depict commonalities in business models, data processing and consequently mimicking behavior.

5.2. Sub-sample: exclusion of mature FinTechs

To test for the influence of more mature FinTechs, we exclude companies, like Hornuf et al. (2020), that employ more than 1000 people or that were founded at least 10 years before our first data-collection period. More experienced and larger companies have more free resources to address legal issues. Especially regarding boilerplate and mimicking behavior, it could be argued that larger or older firms are the industry leaders and are role models for their immediate industry peers and whose privacy practices are mimicked. When excluding these FinTechs, 249 companies in 15 industries remain in the sample. In Tables 9 and 10 in the Appendix, we report summary statistics for the text-feature analysis and find patterns remarkably similar to those for the whole sample analyzed in section 4. For the regression estimates in Tables 11 and 12 in the Appendix, we observe no changes in signs and only small changes in significance of the coefficients. Therefore, we note that it is unlikely that more-mature FinTechs drive our results.

5.3. Pooled OLS with GDPR interaction

To verify our results for the year-wise estimations and post-estimation tests in the seemingly unrelated estimations in section 4, we run an OLS regression with the interaction dummy variable *GDPR*. We estimate the OLS regression to simplify the regression model for the link function in the prior probit specification and pool our observations in a single model with the GDPR interaction to evaluate the effect of the policy intervention simultaneously. The results are reported in Table 13 in the Appendix and mostly show similar patterns in terms of signs and significance of the coefficients compared with the prior model specifications. Additionally, we find that the dummy variable *GDPR* itself has a positive significant influence on level of transparency.

5.4. Industry Boilerplate

In this study, we do not analyze industry-specific boilerplate as Ramadorai et al. (2021) do; instead, we analyze the general influence of the GDPR on potential boilerplate language. However, we additionally calculate in unreported analyses the similarity and distance metrics in relation to the industry average of the FinTech sub-segment. We find only small divergences to the results in Section 3.3.3, which mainly result from the underlying method and are similar to the results of Ramadorai et al. (2021).

6. Conclusion

We empirically study the degree of implementation of the GDPR by FinTech companies operating in Germany. For this purpose, we analyze the privacy statements of 308 FinTechs before and after the GDPR became binding. Employing methods in the field of textual analysis, we analyse their privacy statements. We extend these findings using a content-based approach and link that to company- and industry-specific determinants.

With regard to the text-feature analysis, we document a decrease in readability in conjunction with substantially longer texts and more time required to read the privacy statements. The FinTechs appear to safeguard themselves with exact technical and legal termini and comprehensive statements instead of the user comprehension required by the GDPR. We further find indications of an increase in standardized policy language built on the literature of boilerplate after the GDPR became binding, reducing the informational content that users can draw from the texts. These findings contradict the primary objectives of the GDPR. Further, we analyze the quantity of data processed and transparency and its determinants. We document a significant increase in the quantity of data processed but find no significant changes in the level of transparency. The number of external investors positively influences the quantity of data processed and transparency solely before the GDPR became binding. Regarding cooperation with a bank, we find no significant effects in any specification. Legal capital that we interpret as *ex-ante* founder team dedication is positively related to the level of privacy and is particularly relevant for transparency before the GDPR became binding. These results underline that before the GDPR became binding, externally induced pressure of investors and internal engagement of the founders resulted in better privacy practices. However, the results vanish after the GDPR became binding, as the GDPR made all FinTechs act to ensure data privacy. We also provide evidence that mimicking behavior in terms of industry pressure positively influences data-privacy compliance after the GDPR became binding, which indicates that the GDPR gave companies an incentive to adopt their direct industry peers' data-processing or privacy statements. We ask whether it is possible for a user to give informed consent (art. 7 GDPR) if they cannot transparently capture the language respective to the content of privacy statements. Thus, the question arises whether the GDPR has really fulfilled its promises regarding its main provisions and objectives, especially for the analyzed FinTechs.

Our article has limitations. We mainly refer to the privacy practices that companies declare in their privacy statements, and thus to the supply side of privacy (Ramadorai et al., 2021). Consumers must accept the terms for data processing if they want to use a service or product (Aridor et al., 2020). One avenue for further research is to compare what companies state in their privacy statements with the privacy practices they actually pursue. The results regarding transparency rely on our variable construction. Other approaches and methods can therefore yield different outcomes and insights. Similarly to Goldberg et al. (2021), we can only provide early evidence relating to our data-collection period shortly after the GDPR became binding in May 2018 and how the analyzed companies implemented the regulation at this point.

Finally, our article has practical implications. Legislators as well as policymakers in the EU and other countries that have adopted a privacy regulation related to the GDPR can now see the implications and the unintentional consequences of the regulation. This may pave the way towards future readjustment of the GDPR or give more practical guidance on how to create privacy statements to ensure compliance with the applicable legal standards. Further, our study emphasizes the importance of companies making greater efforts to implement effective privacy practices and communicate them to users in order to benefit from the opportunity to build a competitive advantage.

Figures and Tables

Table 1: List and definitions of all variables. In the following table the abbreviation “D” stands for dummy variable and “D and H (2019)” for Dorfleitner and Hornuf (2019). All variables that are directly included in the analyzes are marked in *italics*.

Variable	Description	Source
<i>Bankcooperation</i>	D: 1 if the Fintech cooperates with a bank, 0 otherwise.	Bank, FinTech websites
<i>No. investors</i>	Logarithm plus 1 of the number of external investment firms and individual investors	BvD Dafne, Crunchbase
<i>Mimic Data Index</i>	Mimicking variable for Data Index	Own calculations
<i>Mimic Transparency Index</i>	Mimicking variable for Transparency Index	Own calculations
<i>Wiener Sachtext</i>	Neuer Wiener Sachtext readability metric	Own calculations
<i>SMOG German</i>	SMOG readability metric (adopted to German language)	Own calculations
<i>SMOG</i>	SMOG readability metric (for English language)	Own calculations
<i>FOG</i>	FOG readability metric (for English language)	Own calculations
<i>No. words</i>	Logarithm of the total number of words	Own calculations
<i>Cosine similarity</i>	Cosine similarity	Own calculations
<i>Jaccard similarity</i>	Jaccard similarity	Own calculations
<i>Euclidean distance</i>	Euclidean distance	Own calculations
<i>Manhattan distance</i>	Manhattan distance	Own calculations
<i>Controls</i>		
<i>Firm age</i>	Logarithm of the age of the FinTech company.	German company register, LinkedIn
<i>Employees</i>	Number of employees (rank variable between 1 and 5)	BvD Dafne, Crunchbase, LinkedIn
<i>City</i>	D: 1 located in a city with more than one million inhabitants, 0 otherwise.	German company register, Websites
<i>Legal capital</i>	D: 1 if a company has a legal form that requires a legal capital of more than 1 EUR, 0 otherwise.	German company register
<i>GDPR</i>	D: 1 if observations are after the introduction of the GDPR on May 25th 2018, representing the post-GDPR period, 0 otherwise.	Websites
<i>Data index</i>	An index aggregating the quantity of data processed. The index adds the hereafter following variables and is divided by 38.	Own calculations
<i>Name</i>	D: 1 if the first and last name are processed, 0 otherwise.	D and H (2019)
<i>Gender</i>	D: 1 if the gender or form of address are processed, 0 otherwise.	D and H (2019)
<i>Title</i>	D: 1 if the title is processed and 0 otherwise.	D and H (2019)
<i>Language</i>	D: 1 if the company processes the language, 0 otherwise.	D and H (2019)
<i>Identifier</i>	D: 1 if the identifier (e.g. user name or ID) is processed, 0 otherwise.	D and H (2019)
<i>Password</i>	D: 1 if the the password is processed, 0 otherwise.	D and H (2019)
<i>Age</i>	D: 1 if the age or date of birth are processed, 0 otherwise.	D and H (2019)
<i>Place of birth</i>	D: 1 if the place or country of birth are processed, 0 otherwise.	D and H (2019)
<i>Address</i>	D: 1 if the address or delivery address or billing address are, processed, 0 otherwise.	D and H (2019)
<i>E-mail address</i>	D: 1 if the e-mail address is processed, 0 otherwise.	D and H (2019)
<i>Phone number</i>	D: 1 if the phone number or mobile number are processed, 0 otherwise.	D and H (2019)
<i>Residence city</i>	D: 1 if the city of residence is processed, 0 otherwise.	D and H (2019)
<i>Residence country</i>	D: 1 if the company processes the country of residence, 0 otherwise.	D and H (2019)
<i>Marital status</i>	D: 1 if the company processes the marital status, 0 otherwise.	D and H (2019)
<i>Occupation</i>	D: 1 if the occupation or employee status are processed, 0 otherwise.	D and H (2019)
<i>Bank</i>	D: 1 if the bank data or account data or payment data are processed, 0 otherwise.	D and H (2019)
<i>PIN</i>	D: 1 if the PIN or TAN are processed, 0 otherwise.	D and H (2019)
<i>Income</i>	D: 1 if the monthly revenues or expenses are processed, 0 otherwise.	D and H (2019)
<i>Tax residency</i>	D: 1 if the tax residency or status are processed, 0 otherwise.	D and H (2019)
<i>Social security number</i>	D: 1 if the social security number is processed, 0 otherwise.	D and H (2019)
<i>Tax id number</i>	D: 1 if the tax identification number is processed, 0 otherwise.	D and H (2019)
<i>Driving license</i>	D: 1 if driving license data is processed, 0 otherwise.	D and H (2019)
<i>Passport, registration</i>	D: 1 if passport and identity card data or the registration number are processed, 0 otherwise.	D and H (2019)
<i>Graduation, qualification</i>	D: 1 if information on graduation or qualifications are processed, 0 otherwise.	D and H (2019)

Continued on Next Page

Variable	Description	Source
Insurance	D: 1 if information on insurance is processed, 0 otherwise.	D and H (2019)
IP-address	D: 1 if the IP-address is processed, 0 otherwise.	D and H (2019)
GPS, location	D: 1 if GPS or location data are processed, 0 otherwise.	D and H (2019)
Personal data published	D: 1 if personal data are published, 0 otherwise.	D and H (2019)
Personal data transfer	D: 1 if personal data are collected from, transferred to or disclosed with third parties, 0 otherwise.	D and H (2019)
Social Plugins, Third party	D: 1 if social plugins are used or third party services are integrated, 0 otherwise.	D and H (2019)
Behavior, usage, movement	D: 1 if behavioral, usage or movement data are processed or tracking services are used, 0 otherwise.	D and H (2019)
Google Analytics	D: 1 if Google Analytics is used, 0 otherwise.	D and H (2019)
Health	D: 1 if health-related data is processed, 0 otherwise.	D and H (2019)
Religion	D: 1 if the religious confession is processed, 0 otherwise.	D and H (2019)
Nationality	D: 1 if the nationality or citizenship is processed, 0 otherwise.	D and H (2019)
Picture	D: 1 if user or title pictures are processed, 0 otherwise.	D and H (2019)
Conversation record	D: 1 if a conversation recording is processed, 0 otherwise.	D and H (2019)
Signature	D: 1 if the signature or sample of writing is processed, 0 otherwise.	D and H (2019)
<i>Transparency index</i>	An index aggregating dimensions of transparency we define hereafter. The index adds the hereafter following variables and is divided by 8.	Own calculations
Data	D: 1 if the company states which personal data are processed, 0 otherwise.	D and H (2019)
Purpose	D: 1 if the company states for what reason or purpose personal data are processed, 0 otherwise.	D and H (2019)
Storage	D: 1 if the company states for how long data are stored or when they are deleted, 0 otherwise.	D and H (2019)
Avoid	D: 1 if the company states if there exists a possibility to avoid data processing, 0 otherwise.	D and H (2019)
Opt-In	D: 1 if the company states whether they have an Opt-In procedure, 0 otherwise.	D and H (2019)
Pseudo	D: 1 if the company states that data are processed pseudonymously, 0 otherwise.	D and H (2019)
Third	D: 1 if the company states which personal data are shared with third parties, 0 otherwise.	D and H (2019)
Third data	D: 1 if the company states with which third parties data are shared, 0 otherwise.	D and H (2019)

End of table

Figure 1: Frequency of occurrence of the FinTech sub-segments following the taxonomy of Dorfleitner et al. (2017), the bars represent the number of companies in each sub-segment, $n=276$.

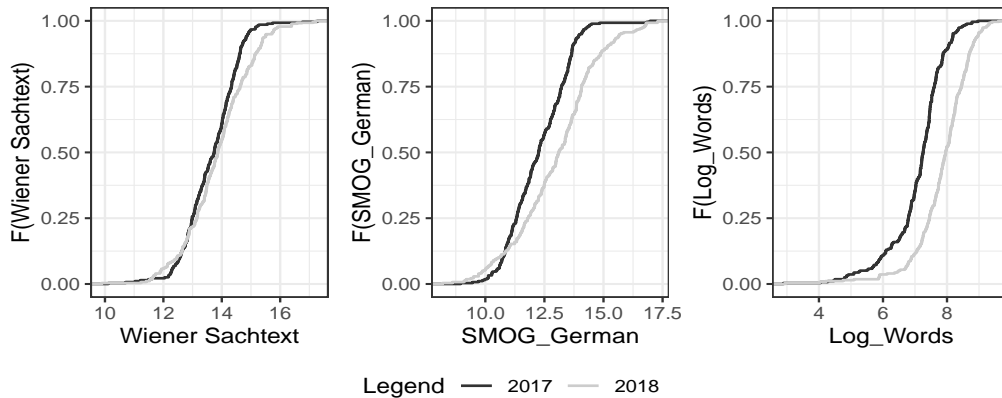

Figure 2: Cumulative distribution function for the readability measures *Wiener Sachtext*, *SMOG German* and *No. words* for before (2017, black) and after (2018, grey) the GDPR became binding.

Table 2: Summary statistics for all our variables, the abbreviation “_pre” indicates before and “_post” after the GDPR became binding, n=276.

Variable	Mean	S.D.	Min	Q1	Median	Q3	Max
Legal capital	0.888	0.316	0.000	1.000	1.000	1.000	1.000
Bankcooperation	0.254	0.436	0.000	0.000	0.000	1.000	1.000
Employees	2.130	1.050	1.000	1.000	2.000	2.000	5.000
City	0.486	0.501	0.000	0.000	0.000	1.000	1.000
