## Policy Innovations and Sectoral Credit Expansion in Kenya

Tiriongo Samuel and Faridah Abdul

KBA Centre for Research on Financial Markets and Policy® Working Paper Series

One Industry. Transforming Kenya.

## **Working Paper Series**

#### **Centre for Research on Financial Markets and Policy**

The Centre for Research on Financial Markets and Policy® was established by the Kenya Bankers Association in 2012 to offer an array of research, commentary, and dialogue regarding critical policy matters that impact on financial markets in Kenya. The Centre sponsors original research, provides thoughtful commentary, and hosts dialogues and conferences involving scholars and practitioners on key financial market issues. Through these activities, the Centre acts as a platform for intellectual engagement and dialogue between financial market experts, the banking sector and the policy makers in Kenya. It therefore contributes to an informed discussion that influences critical financial market debates and policies.

The Kenya Bankers Association (KBA) *Working Papers Series* disseminates research findings of studies conducted by the KBA Centre for Research on Financial Markets and Policy. *The Working Papers* constitute "work in progress" and are published to stimulate discussion and contribute to the advancement of the banking industry's knowledge of matters of markets, economic outcomes and policy. Constructive feedback on the *Working Papers* is welcome. *The Working Papers* are published in the names of the author(s). Therefore their views do not necessarily represent those of the KBA.

## Policy Innovations and Sectoral Credit Expansion in Kenya

By Tiriongo Samuel & Faridah Abdul\* April 2017

## **Abstract**

The paper examines the bank lending channel of monetary policy specifically testing if there is any asymmetric response of sectoral credit to policy innovations on the Central Bank Rate (CBR), Cash Reserve Requirement (CRR), and Foreign Exchange (FX) transactions by CBK. Using a SVAR specification, where the requisite order of variables was quided by literature as well as practical realities in line with the conduct of monetary policy in Kenya. A seven variable SVAR was specified. The findings indicate that there are asymmetric effects of policy innovations on bank reserves when the aggregate credit to private sector is considered. CBR and FX transactions innovations do not seem to significantly impact on bank reserves, even though any changes in the bank reserves when these instruments are actively in use translate to significant changes in overall credit adjustments. But an active use of CRR leads to significant changes in bank reserves. However, when this instrument is active, the resultant change in bank reserves is not translated into credit allocation. Asymmetric effects on sectoral credit allocation when the three policy innovations are triggered was tested. This revealed that when CBR is applied, there is a significant change in bank reserves, which is also transmitted significantly to changes in credit allocation to the key sectors of the economy. And in fact, there is a stronger effect when CRR is used as an instrument of monetary policy. The use of FX transactions in this case does not seem to show significant influence on bank reserves. Even when any changes in bank reserves when FX transactions is used still leads to a significant adjustment in sectoral credit, but to a few sectors. The study therefore recommends a careful choice of monetary policy tool to use if the credit channel of monetary policy is expected to yield desirable results on credit expansion..

## 1.0 Introduction

entral banks world-over that pursue the dual mandate of supporting economic growth and price stability are driven by three main goals: promotion of financial sector development, financial inclusion and alignment of the financial system with the countries' respective development agenda.

> In pursuit of both economic growth and price stability, such central banks have to delicately balance between the achievement of these two objectives since in most cases, they are in conflict. In the execution of its mandate, central bank actions that include adjustments of key policy instruments (herein called policy innovations) would directly impact on decisions by commercial banks on loans extended to the economy.

> The experience of the Central Bank of Kenya is not any different. The country's development blueprint, Vision 2030, which seeks to transform the economy into a newly industrializing middle income economy by 2030, places a heavy responsibility on the financial sector. For instance, under the vision's economic pillar, the main focus of the government as at 2008 was to achieve an economic growth rate of 10% by 2012 and sustain it through to 2030. This was to be driven primarily by an increase in savings ratio from 17% in 2006 to at least 30% by 2012 via enhanced mobilisation of domestic resources to finance higher investment levels, as well as exploring options for tapping increased remittances, foreign direct investment and overseas development assistance. These objectives were to be pursued alongside other long term goals for the sector, that include: improvement in the depth and width of the financial system, enhancement of financial inclusion from both access and usage perspectives; achievement of greater efficiency in the delivery of financial services to ensure that the cost of mobilising resources and allocating these resources becomes

increasingly affordable; and enhancement of the overall stability of the financial system to spur confidence in the sector. Activities for achieving the vision were to be supported by heavy investment in infrastructure as well as a reduction in energy costs (CBK, 2014).

The vision identifies tourism, agriculture (through enhanced value addition), trade, manufacturing sector (with a regional market view), and business process outsourcing as the key sectors to support economic growth. Most importantly, the role of the domestic financial system in mobilizing savings needed for enhanced growth was highlighted as paramount. Mobilization of domestic resources is considered a more stable source of financing than foreign funds, which are predominantly characterised by uncertainties-making them unreliable. They are also volatile and are prone to sudden withdrawals/ outflows which can disrupt economic programmes and also cause devastating economic effects. In fact, Gavin, Hausmann and Talvi (1997), argue that international capital flows are limited in the long run, and as such, a sustained rise in the rate of domestic investment requires a steady growth in the rate of national saving. Experiences from Latin America and East Asia show that saving is an important driving force for economic stability as well as growth. Elbadawi and Mwega (2000) argue that narrowing the savings investment gap contributes to macroeconomic stability and hence economic growth; borrowing

from abroad has adverse effects on the balance of payments as the foreign loans will have to be serviced in the future. In addition, foreign borrowing carries with it foreign exchange risk and thus add to existing menu of risks present in the domestic market.

The efficiency of or rate at which savings are mobilised and channelled to productive use depends, to a large extent, on the existing policy environment; in particular the policy actions taken by the monetary authority. The conduct of monetary policy in Kenya is aimed primarily at achieving price stability but with a secondary objective of supporting economic growth. It is executed through a monetary targeting framework with reserve money (or its componentnet domestic assets of the Central Bank) as the daily operational target, broad money supply as the intermediate target and inflation as the ultimate target . In pursuit of this target, CBK uses a host of instruments including the Central Bank Rate (CBR), cash reserves ratio (CRR), foreign exchange market operations, monetary policy communication including moral suasion, as well as licensing and supervision of financial institutions licensed under the Banking Act. Monetary policy decisions are reflected through changes in the instruments, but the impact on the real sector of the economy depends on the intermediate financial sector's structure. Changes in the instruments are operationalised by open market operations that directly impact on commercial banks' reserves. The framework has remained fairly the same with the CBK continuously refining monetary policy

operations and procedures with a view to enhancing the effectiveness of monetary policy in a changing financial and economic environment

In particular, changes in CBR, CRR as well CBK participation in the foreign exchange market (here regarded as policy innovations) that impact on commercial banks' reserves position influence their lending to the private sector. This is primarily analysed through the credit channel of monetary policy transmission. Mishkin (1995) argues that this channel is based on asymmetric information in financial markets so that a monetary contraction can lead to an increase in the external finance premium faced by borrowers and to a decrease in the loan supply. It amplifies other channels rather than a stand-alone mechanism (Bernanke & Gertler, 1995a) and is usually decomposed into the bank lending channel and the balance sheet channel (Ireland, 2010). Under the bank-lending channel, which is common among developing economies with underdeveloped capital markets, when the monetary authority undertakes a contractionary policy (by either increasing the policy rate, or through foreign exchange sale to the market or increasing cash reserve ratios), the result is a contraction in bank reserves, which induces banks to reduce their lending. This in turn makes households and business/firms to reduce their consumption and investment spending-and thus output and prices.

Through the balance sheet channel and in the presence of financial market imperfections, firms' cost of accessing credit, whether from banks or any other external source, increases when the strength

of their balance sheets deteriorates. In this case, an increase in interest rates following a tight monetary policy may reduce the capitalization value of the firms' long-term assets, weakening their balance sheets and increasing their cost of accessing credit. This reduces borrowing, investment and output (Davoodi et al., 2013). A worsening of balance sheets reduces the net worth of the borrowers. Banks then need to tighten credit profiling of borrowers to minimize incidences of non-performing loans. This reduces the amount of loans made available by banks to borrowers- thus domestic demand and output. In this analysis, the key assumption is that bank loans are firms' principal sources of funds, for which few close substitutes exist (Mishkin, 1995). This is true for the case of Kenya where the domestic capital markets are still underdeveloped.

There is vast empirical literature on monetary transmission from policy actions through commercial banking decisions to real output and prices. However, most of the studies have primarily focused on developed economies. The most distinguishing characteristic of monetary policy transmission in developed countries is the focus on prices (interest rate, exchange rate, and other asset prices) rather than quantities (money, credit, base money, bonds, foreign assets, etc.). However, there are arguments that monetary policy transmission mechanisms in low (and some middle) income countries focus more on the quantities rather than prices. These differences are often attributed to weak institutional frameworks, oligopolistic banking structures, shallow financial markets, and extensive central bank interventions in

foreign exchange markets in low and many middle income countries (see for instance Christiano et al. 2010).

Mishra et al., (2010) argue strongly for greater effectiveness of credit channel (especially the bank lending channel) than any other channel in a cross-country study of low income countries. They provide strong evidence of a weak interest rate pass-through—from central bank lending rates to money market rates and from money market rates to commercial banks' lending rates. In addition, they argue that in most Sub-Saharan Africa (SSA) countries monetary policy shocks (defined by changes in reserve money) affect output significantly, but the impact of the shocks on inflation depends on the monetary policy instrument adjusted. For instance, while a decline in reserve money (the operating target for many SSA countries) does not reduce inflation significantly, an increase in the central bank discount rate or policy rate (the operating target for a small number of SSA countries) has a statistically significant impact on inflation (IMF, 2010). Such findings reflect the asymmetric effects of monetary policy actions on macroeconomic variables of interest (growth and inflation) and, thus point to the need to conduct analyses on transmission mechanism through the credit channel but focusing on the adjustments of different policy instruments.

A number of studies have been conducted on monetary policy transmission in Kenya but mainly focusing on the changes in the policy rate (see for

instance: Cheng, 2006; Buigut, 2009; Misati et al., 2010; Sichei & Njenga, 2010; and Mwega, 2013) with little focusing on the treasury bill rate (Buigut, 2010) and on broad supply (Maturu, 2011), as measures of policy shocks. From these studies, none attempted to analyse the role of changes in other policy actions such as foreign exchange market participation and adjustments in the CRR. Nevertheless, Sichei & Nienga (2010) attempted to cover the bank lending channel in depth. The study employed 3-Stage Least Squares estimation techniques on static annual data (2001-2008) for 37 commercial banks to investigate whether monetary policy had differential effects on banks and whether the credit channel is more operative through loan demand or loan supply. Findings indicated that banks contract loan supply in response to monetary tightening, thus reflecting credit rationing. This shows strong evidence for the effectiveness of the banklending channel in Kenya but through quantities rather than price:- the lending rate.

Studies on transmission mechanisms reviewed so far show no attempt to explore the effect of other monetary policy actions such as changes in central bank foreign transactions with the banking industry and CRR on commercial bank reserves and lending in the credit channel. This paper intends to fill-in this gap and provide empirical evidence for Kenya using shocks on CBR, CRR and foreign exchange transactions as policy shocks (innovations) that potentially affect output and prices through the commercial bank lending channel of monetary policy. Specific research auestions include:

- Do different policy actions/ innovations (as measured by changes in CBR, CRR and foreign exchange transactions) affect sectoral credit expansion differently? Or establish whether there is evidence of sectoral asymmetric response of credit to the policy innovations?
- (ii) How does sectoral credit expansion (in terms of magnitude and transmission lags) respond to the different policy innovations? Is their evidence of credit rationing to some sectors of the economy, and if so, to what degree?

## 2.0 Methodology

n analysing monetary policy transmission mechanisms, many authors adopt the Vector Autoregression (VAR) approach pioneered by Sims (1980). This approach is useful tool for analysing situations with short data series, recent history of macroeconomic instability, and with significant structural changes that make reliance on structural models questionable.

It sidesteps the need for structural modelling by treating every endogenous variable as a function of exogenous variables as well as the lagged values of all the endogenous variables in the system. In addition, it explicitly recognizes the simultaneity between monetary policy and macroeconomic developments (reaction function) as well as the dependence of economic variables on monetary policy (Dabla-Norris & Floerkemeier, 2006). Most studies in low income countries as reviewed by Mishra et al., (2010) have used structural recursive VAR that facilitates analysis of impulse responses and forecast error variance decomposition. Structural VAR is appropriate for studying the impact of interventions or policy changes in the economy. This approach assumes a recursive relationship between errors of reduced form VAR.

The paper sets out to analyse the effects of policy signals from changes in the main policy instruments; the CBR, CRR and foreign exchange transactions between CBK and the commercial banks on sectoral credit expansion in Kenya. The policy signals directly influence the level of bank reserves and thus affect commercial banks' lending decisions. Credit expansion to the sectors of the economy is used to capture the bank lending channel of monetary policy. We adopt a recursive structural VAR framework. The variables of interest (denoted by *matrix X*) include: the logarithm of real GDP (RGDP), logarithm of credit to private sector (Credit), logarithm of bank reserves (Reserves), logarithm of price level (CPI), nominal exchange rate (NER), the logarithms of Central Bank Rate (CBR) and the average lending rate (Lrate). This represented as follows:

$$X_t = [RGDP_t, CPI_t, CBR_t, Reserves, Lrate_t, Cred_t, NER_t]$$
 .....(1)

Minimization of multicollinearity commonly present in VAR models is done by using granger causality analyses before we examine transmission lags and magnitudes using impulse response functions and forecast error variance decompositions as proposed by Enders (2006). Both impulse response functions and variance decomposition are sensitive to ordering of the variables in the VAR specification. Theoretical arguments and the operational realities in the conduct of monetary policy in Kenya are employed to guide variable ordering in the analyses, as in **Model (1)**. RGDP is ordered first since it is assumed not to react contemporaneously to shocks from other variables in the system. Second is the CPI, which is assumed not to react contemporaneously to shocks from all other factors except RGDP. Third in the ordering is the shortterm policy rate (CBR). The other measures of policy actions are replaced in this position one at a time. Fourth in the order are bank reserves to capture the

first host of policy shocks in the credit channel.

Fifth is the commercial banks' average lending interest rate which is assumed to be adjusted based on volumes of bank reserves and policy rate changes. Sixth is credit extended to the private sector which is placed after the lending rate because the private sector is assumed to respond (perhaps not contemporaneously) by changing their demand for loans following adjustments in lending rates. As such, credit to private sector is allowed to respond to changes in interest rates. This ordering is convenient to allow a loosening of monetary policy to be transmitted to credit expansion, subsequently affecting output and inflation with a lag (if the credit channel is effective). After credit to private sector, the nominal effective exchange rate is ordered last because it responds contemporaneously to shocks on all macroeconomic variables in the system identified.

The following system of **equations (2)** represents the structural VAR model of the system<sup>1</sup>.

$$\begin{split} RGDP_{t} &= a_{10} - a_{11}CPI_{t} - a_{12}CBR_{t} - a_{13}\operatorname{Re}\,serves_{t} - a_{14}Lrate_{t} - a_{15}Cred_{t} - a_{16}NER_{t} + A_{11}RGDP_{t-1} \\ &+ A_{12}CPI_{t-1} + A_{13}CBR_{t-1} + A_{14}\operatorname{Re}\,serves_{t-1} + A_{15}Lrate_{t-1} + A_{16}Cred_{t-1} + A_{17}NER_{t-1} + \varepsilon_{t}^{RGDP} \\ CPI_{t} &= a_{20} - a_{21}RGDP_{t} - a_{22}CBR_{t} - a_{23}\operatorname{Re}\,serves_{t} - a_{24}Lrate_{t} - a_{25}Cred_{t} - a_{26}NER_{t} + A_{21}RGDP_{t-1} \\ &+ A_{22}CPI_{t-1} + A_{23}CBR_{t-1} + A_{24}\operatorname{Re}\,serves_{t-1} + A_{25}Lrate_{t-1} + A_{26}Cred_{t-1} + A_{27}NER_{t-1} + \varepsilon_{t}^{CPI} \end{split}$$

<sup>1.</sup> We use a lag length of 1 just for demonstration, but the appropriate optimal lag length is established empirically.

$$\begin{split} CBR_t &= a_{30} - a_{31}RGDP_t - a_{32}CPI_t - a_{33}\operatorname{Re}\,serves_t - a_{34}Lrate_t - a_{35}Cred_t - a_{36}NER_t + A_{31}RGDP_{t-1} \\ &+ A_{32}CPI_{t-1} + A_{33}CBR_{t-1} + A_{34}\operatorname{Re}\,serves_{t-1} + A_{35}Lrate_{t-1} + A_{36}Cred_{t-1} + A_{37}NER_{t-1} + \varepsilon_t^{CBR} \end{split}$$

$$\begin{aligned} & \text{Re}\,serves_{t} = a_{40} - a_{41}RGDP_{t} - a_{42}CPI_{t} - a_{43}CBR_{t} - a_{44}Lrate_{t} - a_{45}Cred_{t} - a_{46}NER_{t} + A_{41}RGDP_{t-1} \\ & + A_{42}CPI_{t-1} + A_{43}CBR_{t-1} + A_{44}\operatorname{Re}\,serves_{t-1} + A_{45}Lrate_{t-1} + A_{46}Cred_{t-1} + A_{47}NER_{t-1} + \varepsilon_{t}^{Re}\,serves \end{aligned}$$

$$\begin{split} Lrate_{t} &= a_{50} - a_{51}RGDP_{t} - a_{52}CPI_{t} - a_{53}CBR_{t} - a_{54}\operatorname{Re}serves_{t} - a_{55}Cred_{t} - a_{56}NER_{t} + A_{51}RGDP_{t-1} \\ &+ A_{52}CPI_{t-1} + A_{53}CBR_{t-1} + A_{54}\operatorname{Re}serves_{t-1} + A_{55}Lrate_{t-1} + A_{56}Cred_{t-1} + A_{57}NER_{t-1} + \varepsilon_{t}^{Lrate} \end{split}$$

$$\begin{aligned} &Cred_{t} = a_{60} - a_{61}RGDP_{t} - a_{62}CPI_{t} - a_{63}CBR_{t} - a_{64} \operatorname{Re} serves_{t} - a_{65}Lrate_{t} - a_{66}NER_{t} + A_{61}RGDP_{t-1} \\ &+ A_{62}CPI_{t-1} + A_{63}CBR_{t-1} + A_{64} \operatorname{Re} serves_{t-1} + A_{65}Lrate_{t-1} + A_{66}Cred_{t-1} + A_{67}NER_{t-1} + \varepsilon_{t}^{Cred} \end{aligned}$$

$$\begin{split} NER_t &= a_{70} - a_{71}RGDP_t - a_{72}CPI_t - a_{73}CBR_t - a_{74} \operatorname{Re} serves_t - a_{77}Lrate_t - a_{75}Cred_t + A_{71}RGDP_{t-1} \\ &+ A_{72}CPI_{t-1} + A_{73}CBR_{t-1} + A_{74}\operatorname{Re} serves_{t-1} + A_{75}Lrate_{t-1} + A_{76}Cred_{t-1} + A_{77}NER_{t-1} + \varepsilon_t^{NER} \end{split}$$

where  $\varepsilon_t^{RGDP}$ ,  $\varepsilon_t^{CPI}$ ,  $\varepsilon_t^{CBR}$ ,  $\varepsilon_t^{Reserves}$ ,  $\varepsilon_t^{Lrate}$ ,  $\varepsilon_t^{Cred}$   $\varepsilon_t^{NER}$ , are uncorrelated structural disturbances. Since VAR models are estimated in their standard/reduced form, this study considers a transformation of the above structural representation into reduced form, by shifting the contemporaneous effects to the left hand side of the respective equations. This in matrix form yields:

$$\begin{pmatrix} 1 & a_{11} & a_{12} & a_{13} & a_{14} & a_{15} & a_{16} \\ a_{21} & 1 & a_{22} & a_{23} & a_{24} & a_{25} & a_{26} \\ a_{31} & a_{32} & 1 & a_{33} & a_{34} & a_{35} & a_{36} \\ a_{41} & a_{42} & a_{43} & 1 & a_{44} & a_{45} & a_{46} \\ a_{51} & a_{52} & a_{53} & a_{54} & 1 & a_{55} & a_{56} \\ a_{61} & a_{62} & a_{63} & a_{64} & a_{65} & 1 & a_{66} \\ a_{71} & a_{72} & a_{73} & a_{74} & a_{75} & a_{76} & 1 \end{pmatrix} \begin{pmatrix} RGDP_t \\ CPI_t \\ CBR_t \\ Beserves_t \\ Cred_t \\ NER_t \end{pmatrix} = \begin{pmatrix} a_{10} \\ a_{20} \\ a_{30} \\ a_{40} \\ a_{50} \\ a_{60} \\ a_{70} \end{pmatrix} + \begin{pmatrix} A_{11} & A_{12} & A_{13} & A_{14} & A_{15} & A_{16} & A_{17} \\ A_{21} & A_{22} & A_{23} & A_{24} & A_{25} & A_{26} & A_{27} \\ A_{31} & A_{32} & A_{33} & A_{34} & A_{35} & A_{36} & A_{37} \\ A_{41} & A_{42} & A_{43} & A_{44} & A_{45} & A_{46} & A_{47} \\ A_{51} & A_{52} & A_{53} & A_{54} & A_{55} & A_{56} & A_{57} \\ A_{61} & A_{62} & A_{63} & A_{64} & A_{65} & A_{66} & A_{67} \\ A_{71} & A_{72} & A_{73} & A_{74} & A_{75} & A_{76} & A_{77} \end{pmatrix} \begin{pmatrix} \mathcal{E}^{CDP}_{t-1} \\ CPI_{t-1} \\ CBR_{t-1} \\ Cred_{t-1} \\ NER_{t-1} \end{pmatrix} + \begin{pmatrix} \mathcal{E}^{KODP}_{t-1} \\ \mathcal{E}^{CPI}_{t-1} \\ \mathcal{E}^{CPI}_{t-1} \\ \mathcal{E}^{RODP}_{t-1} \\ \mathcal{E}^{CPI}_{t-1} \\ \mathcal{E}^{CBR}_{t-1} \\ \mathcal{E}^{CBR}_{t-1} \\ \mathcal{E}^{CROP}_{t-1} \\ \mathcal{E}^{CPI}_{t-1} \\ \mathcal{E}^{CBR}_{t-1} \\ \mathcal{E}^{CPI}_{t-1} \\ \mathcal{E}^{CBR}_{t-1} \\ \mathcal{E}^{CPI}_{t-1} \\ \mathcal$$

This can be represented as:

$$AX_{t} = \Gamma_{0} + \Gamma_{1}X_{t-1} + \varepsilon_{t} \tag{4}$$

Assuming that the inverse of A (matrix of coefficients capturing contemporaneous effects between variables) exists, then matrix (4) can be written as

$$X_{t} = A^{-1}\Gamma_{0} + A^{-1}\Gamma_{1}X_{t-1} + A^{-1}\varepsilon_{t}$$
 (5)

This can further be simplified to yield equation (9), as

$$X_{t} = \alpha_{0} + B_{1}X_{t-1} + e_{t}, \tag{6}$$

where  $\alpha_0 = A^{-1}\Gamma_0$ ,  $B_1 = A^{-1}\Gamma_1$  and  $e_t = A^{-1}\varepsilon_t$ . Equation (6) is a reduced-form model representation of equation 3. The matrix  $e_t$  is a vector of reduced form disturbances, which are assumed to have zero mean, constant variance and zero auto-covariance. The matrix  $B_1$  can be written in a general form to represent an nth order lag polynomial to capture n lags in the relationships. The variance covariance matrix of reduced-form disturbances is given as  $\sum_{e} = Ee_{t}e_{t}^{'}$ .

Once consistent estimates of  $B_1$ ,  $\alpha_0$  and  $\Sigma$  have been obtained, the structural parameters can be recovered by pre-multiplying the reduced-form parameters by the non-singular matrix A. It is assumed that the structural disturbances are uncorrelated with each other, i.e. the variance-covariance matrix  $\Sigma_{\varepsilon} = E \varepsilon_t \varepsilon_t$  is diagonal. The relationship between the structural disturbances  $\mathcal{E}_t$  and the reducedform disturbances  $e_t$  is described by  $\Phi \varepsilon_t = A e_t$ . However, without restrictions on the parameters of A and  $\Phi$  this model is not identified. This study

performs identification using the recursive approach as proposed by Sims (1980). This approach requires that the matrix  $\Phi$  is restricted to an identity matrix and matrix A to a lower triangular matrix with unit diagonal. This implies a decomposition of the variance-covariance matrix of the form:

$$\sum_{e} = A^{-1} \Sigma_{\varepsilon} (A^{-1})'_{\dots}$$
 (7)

This is generated from the Cholesky decomposition  $\sum_{e} = PP'$  by defining a diagonal matrix  $\varphi$  which has the same diagonal as  ${\it P}$  and by specifying  $A^{-1} = P\varphi^{-1}$  and  $\Sigma_{\varepsilon} = \varphi\varphi'$ , i.e. the elements of the main diagonal of  $\varphi$  and P are equated to the standard deviation of the respective structural shock.

Based on the ordering of variables earlier outlined, the relationship between the reduced form and structural disturbances therefore takes the form represented by matrix (8).

$$\begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ a_{21} & 1 & 0 & 0 & 0 & 0 & 0 \\ a_{31} & a_{32} & 1 & 0 & 0 & 0 & 0 \\ a_{41} & a_{42} & a_{43} & 1 & 0 & 0 & 0 \\ a_{61} & a_{62} & a_{63} & a_{64} & a_{65} & 1 & 0 \\ a_{71} & a_{72} & a_{73} & a_{74} & a_{75} & a_{76} & 1 \end{pmatrix} \begin{pmatrix} e_t^{RGDP} \\ e_t^{CPI} \\ e_t^{CRR} \\ e_t^{Cred} \\ e_t^{NSE} \\ e_t^{NER} \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \varepsilon_t^{RGDP} \\ \varepsilon_t^{CPI} \\ \varepsilon_t^{CRR} \\ \varepsilon_t^{Cred} \\ \varepsilon_t^{NSE} \\ \varepsilon_t^{NSE} \\ \varepsilon_t^{NER} \end{pmatrix}$$

Since the objective of this study is to investigate how policy innovations have impacted on the credit channels of monetary policy transmission, the study considers to undertake analyses using the policy innovation variables (CBR, CRR and Foreign exchange transactions volume), one at a time and the results of

the transmission compared. Credit is also analysed at both overall level and sectoral level, one sector at a time. The speed and magnitude of transmission are then compared in different periods and differences (if any) attributed to the innovations.

## 3.0 Empirical Procedure

The standard practice in analyses using VAR framework is to focus on the impulse response functions and forecast error variance decomposition, and not the coefficients of the VAR model. The impulse response functions trace out the response of current and future values of the set of variables to a one standard deviation increase in each of the variables in the system.

> The forecast error variance decomposition helps to account for variations in variables overtime. It apportions the variations in each variable to shocks from within and from other variables in the system.

> The study undertakes structural VAR estimations involving all the variables outlined in equation (1) but incorporating all the policy innovations and sectoral credit, one at a time. The results are compared to isolate the transmission of one policy innovation through the overall as well as sectoral credit expansion. As in many VAR models, analysis is done in levels. This allows for implicit cointegrating relationships in the data. Imposing cointegrating restrictions on a VAR in levels could increase efficiency in the estimation. Sims (1980) recommends against differencing the data even if the variables contain a unit root, as the goal of the VAR analysis is to determine interrelationships among the variables, not parameter estimates. Differencing throws away information concerning the co-movements in the data such as the possibility of cointegrating relationships (Enders, 1995). All the variables are expressed in logarithms<sup>2</sup>. The optimal lag length of the VAR estimation is selected using five standard tests, namely

<sup>2.</sup> Interest rates are expressed in logarithms after transforming appropriately as follows:  $Ln(1 + r/400) \approx$ r/400 where r = annual interest rate in %.

sequential modified LR test (LR), Final Prediction error (FPE), Akaike Information Criteria (AIC), Schwarz Information Criteria (SIC) and Hannan–Quinn information criteria (HQ)<sup>3</sup>.

The paper uses quarterly data spanning 1996Q1-2015Q4 on the following variables: RGDP, CPI, policy

rate (CBR after June 2006 and the TBR+3% rule before June 2006) CRR, CBK foreign exchange transaction volumes, average lending rate, total credit to private sector, bank reserves, nominal exchange rate and the stock market price index. The choice of this study period is limited by availability of data on key variables such real GDP.

 $<sup>3. \</sup>quad A \ brief review of the lag selection method is provided in Table 3 in the Appendix.$ 

## **Empirical Results**

Data on endogenous variables i.e. real Gross Domestic Product (RGDP), Consumer Price Index (CPI), the average lending rate (Lrate), Credit to private sector (CREDIT), and the nominal exchange rate (NER), used in the study is presented graphically in Figure 1 in the Appendix.

The exogenous variables used in the study are adopted from Cheng (2006) include a proxy for foreign interest rates (captured by the US Treasury bill rate) i.e. USTbill, as well as seasonal dummies (quarterly)<sup>4</sup>. The use of the US Treasury bill rate is also included in the analysis to account for interest rate parity. Seasonal dummies are included in the analyses to account for seasonal effects. In the analysis, monetary policy stance is represented by the bank rate (CBR), cash reserve requirement and CBK foreign exchange transaction volumes

**Table 1** in the appendix presents the results of the full sample VAR lag order selection criteria based on five tests, namely sequential modified LR test (LR), Final Prediction Error (FPE), Akaike Information Criteria (AIC), Schwarz Information Criteria (SC) and Hannan-Quinn information criteria (HQ). A majority of the tests (FPE, SC, and HQ) support a maximum lag of 1 quarter for the VAR. To ascertain the stability of the estimated SVAR, an examination of the inverse roots of the characteristic polynomial shows that all the roots lie within the unit circle, as shown in **Figure 2**.

**Table 2** in the Appendix displays the VAR Granger causality (block exogeneity test) results. The results show that the most important

<sup>4.</sup> Dummies for guarter 1, 2 and 3 are included in the analyses, except guarter 4 dummy (to avoid dummy variable trap)

relationships at 10% level of significance (or higher) are from CPI, CREDIT, NER to Real GDP; RGDP, Bank Reserves, CREDIT and NER to prices; real GDP and CREDIT to the CBR; CPI, and NER to Bank Reserves, RGDP and CBR to the LRATE; CPI, Bank Reserves and LRATE to CREDIT; and finally, real GDP and LRATE to NER. The results indicate strong bidirectional causality pattern thus justifying the use of VAR approach. We then consider the impulse response functions and the forecast error variance decomposition.

## Impulse Response Functions (IRFs) and Forecast Error Variance Decompositions (VD)

The analyses of IRFs and VD is undertaken focusing on the effect of the changes in the policy innovations on the bank reserves and ultimately on the credit to private sector (CREDIT), both at aggregate level and at sector level; representing an in-depth analyses of the credit channel of monetary policy transmission. Unlike in other past monetary policy transmission channels that focus on impact of policy innovations on output and prices, this study particularly seeks to tease out information on the link between policy changes and credit allocation scheme in Kenya. Since policy innovations in practice do not directly affect credit supply, but through changes in bank reserves, A two stage analysis was conducted. The first stage focuses on the impact of policy innovations on bank reserves. The second stage then analyses the impact of changes in bank reserves on credit allocation (both at aggregate and sectoral level).

Figure 3a presents the two stage results on IRFs of changes in CBR on bank reserves (Left panel) and IRFs of changes in Bank Reserves on CREDIT (right panel)<sup>5</sup>. The IRFs trace out a one standard deviation shock on the policy variable on the bank reserves and also analyse a one standard deviation shock of the bank reserves on credit allocation. It is evident from the results that a one standard deviation positive shock in the CBR does not significantly impact on bank reserves, when analysed at 5% level of significance. While this result questions the effectiveness of the CBR in influencing credit allocation in Kenya, it also justifies our intention to measure the effectiveness of other policy innovations. However, the VAR specification that incorporates CBR allows for a one standard deviation positive shock in bank reserves to significantly affect the overall credit allocated to the private sector at least from the 2nd period. This effect is sustained for five guarters following the shock <sup>6</sup>.

The forecast error variance decomposition of bank reserves when CBR is considered as the policy variable are then presented. This apportions the variations in bank reserves to shocks in the SVAR variables. The results indicate that in the first four quarters, CBR is the second most important variable that accounts for variations in bank reserves (despite being insignificant-accounting for less than 7% of variations) while own innovations account for over 73% (**Table 1**).

<sup>5.</sup> Test for stability results using the inverse roots of the AR characteristic polynomial are provided in appendix Figure 5a-c. They indicate stability of the SVAR specification.

<sup>6.</sup> We exclude the IRFs results for the other variables in the VAR due to space limitation. The results are available upon request.

Cholesky Ordering: RGDP CPI CBR RESERVES LRATE CREDIT NER

Moreover, a one standard deviation positive shock on the CRR leads to a significant decrease in bank reserves but only in the second quarter after the shock. The one period lag in the impact of CRR increase on reserves is attributed to the fact that a majority of the CRR adjustments in the sample period were effective one month after they were made; which may coincide with the next guarter<sup>7</sup>. However, there is no significant transmission of the impulse from reserves

to commercial banks' credit allocation; indicating the ineffectiveness of the CRR as a policy tool to influence credit allocation (Figure 3b). The forecast error decomposition of the variation in bank reserves show that in the first four quarters, CRR accounts on average for less than 8.5% of the variations in bank reserves. while own innovations account for over 72% of the variations (Table 2).

Cholesky Ordering: RGDP CPI CRR RESERVES LRATE CREDIT NER

When foreign transactions with the banking sector are used as policy impulses, a one standard deviation positive shock on the FX transactions seems not significantly influence commercial bank reserves. However, the second stage of the transmission indicates that a one standard deviation positive shock causes a significant increase in credit allocated to the private sector, but the effect is significant from the

2nd guarter to the 7th guarter (**Figure 3c**). In the first four quarters, only an average of about 0.6% of the variation in bank reserves are accounted for by changes in foreign exchange transactions of the central bank with commercial banks. A large proportion of the variations (over 85%) in bank reserves are accounted for by its own changes (**Table 3**).

Cholesky Ordering: RGDP CPI FX RESERVES LRATE CREDIT NER

From the above analyses, it is evident that among the three policy innovations (CBR, CRR & FX transactions) only CRR changes have significant influence on bank reserves. But when CRR changes are instituted, there is no significant influence of changes in bank reserves on overall credit allocation by the banking sector. However, when CBR changes are effected or FX transactions are undertaken, there seems to be a stronger effect of bank reserves on credit allocation. This evidence indicates evidence of asymmetric effects of policy innovation on bank reserves and on credit allocation behaviour of the banking sector. We then proceed to also establish the effect of the policy innovations on sectoral credit allocation in the banking sector.

Figure 4a shows the results on IRFs of changes in bank reserves when CBR is adjusted. In this case, instead of using overall credit allocation, we consider sectoral credit for the 11 sectors (agriculture, building & construction, mining, trade, manufacturing, transport, real estate, households, finance & insurance, consumer durables and business activities). The results show that a one standard deviation innovation on the CBR significantly reduces bank reserves within the first 2 quarters following the innovation.

The impact of the changes in bank reserves on sectoral credit is heterogeneous. For instance, while a one standard deviation positive increase in bank reserves leads to a significant increase in bank credit

to agriculture, trade, manufacturing, real estate and business activities (though with varying degrees of influence), credit expansion to the building & construction, mining, transport, households, finance & insurance and for purchase of consumer durables is not significantly affected. In particular, a positive (one standard deviation) shock on bank reserves significantly increases credit to agriculture sector but with a lag of 5 guarters, and to trade activities from the 2nd -through to the 9th quarter. Similarly, an increase in bank reserves increases credit to manufacturing sector from the 2nd to 10th quarter after the shock while credit to real estate and business activities would increase from the 2nd to 8th guarter and 2nd to 9th quarter, respectively (lower panel of Figure 4a).

Figure 4a: IRFs of CBR policy innovations on Bank Reserves and Reserves on Sectoral Private **Sector Credit** 

Similarly, we map out the effect of a one standard deviation positive shock on the CRR in place of the CBR. It is evident that a one standard positive shock on CRR significantly within the period of the shock but the subsequent increases in bank reserves die out slowly but significantly up to the fourth lag. The initial increase in bank reserves reflects the one month lag in effecting CRR changes that banks are given to prepare to meet the CRR. The subsequent decay in the increase in bank reserves represents the implementation of prior CRR adjustments. It appears that banks in Kenya over provide for meeting CRR and thus, bank reserves build up during periods of CRR adjustments. This is perhaps because of the heavy penalties that CBK applies in case

of non compliance (upper panel of **Figure 4b**).

An analysis of the effect of changes in bank reserves on sectoral credit indicates that upward adjustments in bank reserves, in an environment when the policy instrument applied by CBK is CRR, significantly increases credit allocated by the banking sector to agriculture (from the 6th to 10th period), building & construction (from 7th to 10th period) trade (from 2nd to 10th period), manufacturing (from 2nd to 10th period), real estate (after 2 periods) and business activities (from the 3rd to 9th period). The increase in credit allocation to the rest of the sectors is established to be insignificant.

Figure 4b: IRFs of CRR policy innovations on Bank Reserves and Reserves on Sectoral Private **Sector Credit** 

Response to Cholesky One S.D. Innovations ± 2 S.E.

Finally, if the CBK pursues monetary adjustments through unsterilized foreign exchange transactions, the IRFs functions that measure a one standard increase in foreign exchange transactions does not seem to significantly impact on commercial bank reserves. Here, we assume that CBR and CRR remain fixed (Upper panel of Figure 4c). However, in this environment, any build-up in bank reserves cause significant increase in credit allocated to building &

construction (but from the 4th to 9th period), trade, manufacturing and real estate ( all from the 2nd to 10th period). In addition, credit to business activities increases from the 2nd to the 9th period (lower panel of Figure 4c). Credit to the rest of the sectors does not seem to respond significantly to changes in bank reserves when CBK uses FX transactions as the policy tool

Figure 4c: IRFs of Foreign Exchange Transaction Volumes policy innovations on Bank Reserves and Sectoral Private Sector Credit

in credit to trade (7%), building & construction (5%), manufacturing (4%), and real estate (3%).

Analyses of the VD (Tables 3a-c in the appendix) show that the variations in sectoral credit that is accounted for by policy innovations vary across sectors. However, own sectoral credit innovations account for the largest proportions of changes in the sectoral credit. In the order of importance in terms of accounting for variations in sectoral credit (analysed in the first four quarters), CBR accounts for variations in credit to building & construction (21%), consumer durables (7%), transport (4%) and finance (4%). Similarly, changes in CRR account for variations in credit to building & construction (9%), trade (7%), and finance (3%). FX transactions changes account for variations

Changes in bank reserves similarly have asymmetric effects on sectoral credit depending on the policy instrument adopted by CBK. For instance, when CBR is used to signal stance of monetary policy, changes in bank reserves account (ordered from largest to smallest) for variations in credit allocated to real estate (18%), manufacturing (15%), business activities (12%), and agriculture (4%). When the policy instrument is CRR, changes in bank reserves account for variations in credit to real estate (13%), trade (9%), households (8%), finance & insurance (6%), and agriculture (5%). In the event that CRR and CBR are fixed and CBK uses FX transactions as the instrument of monetary policy to influence bank reserves, the resultant change in bank reserves significantly account for variations in credit to real estate (18%), manufacturing (17%), business activities (11%), trade (8%) and building & construction (7%).

# **5.0 Conclusions and Policy Implications**

The objective of this study was to measure whether there is any asymmetric response of sectoral credit to the policy innovations by three instruments (CBR, CRR, and FX transactions by CBK).

In addition, the paper also aimed at measuring the magnitude of variation in credit allocation due to changes on bank reserves occasioned by varied policy innovations. Using a SVAR specification, where the requisite order of variables was guided by literature as well as practical realities in line with the conduct of monetary policy in Kenya, we specify a seven variable VAR. The paper examines the credit channel (especially the bank lending channel) of monetary policy by first, testing the effect of the three different policy innovations on bank reserves, then second, examining the impact of changes in bank reserves on overall credit as well as disaggregated sectoral credit allocations. These were examined using IRFs and VD and significance criteria judged on the basis of a 5% level of significance.

Results indicate that there are asymmetric effects of policy innovations on bank reserves when we consider the aggregate credit to private sector. In particular, a one standard deviation policy shock on the CBR does not result in a significant adjustment on the bank reserves. However, when CBR is used by CBK as a policy instrument, any form of adjustment in bank reserves leads to a significant change in credit allocation to the private sector. This is also experienced when FX transactions are used by CBK as an instrument of monetary policy (as CBR and CRR remain inactive). On the other hand, an adjustment in CRR leads to a significant change in bank reserves. However, when

this instrument is active, the resultant change in bank reserves is not translated into credit allocation

Asymmetric effects in sectoral credit allocation when the three different policy instruments are used was tested. The findings were that when CBR is applied by CBK, there is a significant change in bank reserves, which is also transmitted significantly to changes in credit allocation to key sectors of the economy (agriculture, trade, manufacturing, real estate and business activities).

When CBK uses CRR, there is a similar effect on bank reserves and sectoral credit allocation, but an additional sector that experiences significant adjustment in credit allocation is building & construction. As such, more sectors are affected when CRR is used as opposed to when CBR is used. The reason could be attributed to the fact that CRR is a direct instrument of monetary policy that does not rely on any other central bank operation for it to affect bank reserves. CBR adjustments affect bank reserves once the Repo market implements consistent

actions to operationalise the CBR signal. For the use of FX transactions as a policy instrument, the results show that this approach does not yield a significant change in bank reserves. Despite this, any form of changes in bank reserves in this environment similarly causes a significant change in credit to building & construction, trade, manufacturing, real estate and husiness activities

From the above results, this paper concludes that different policy instruments yield different effects on credit allocation, and the allocation differs across the sectors of the economy. We therefore recommend that for monetary policy actions to achieve desirable effects on credit expansion there is need for CBK to consider the appropriate instrument to use. This includes a stronger consideration on the economic performances of the different sectors of the economy so that challenges with absorption of credit do not yield undesirable outcomes such as build up in demand-driven inflationary pressure during periods of loose monetary policy.
