Specification and Estimation of Spatial Autoregressive Models with Autoregressive and Heteroskedastic Disturbances

Abstract

One important goal of this study is to develop a methodology of inference for a widely used Cliff-Ord type spatial model containing spatial lags in the dependent variable, exogenous variables, and the disturbance terms, while allowing for unknown heteroskedasticity in the innovations. We first generalize the generalized moments (GM) estimator suggested in Kelejian and Prucha (1998, 1999) for the spatial autoregressive parameter in the disturbance process. We prove the consistency of our estimator; unlike in our earlier paper we also determine its asymptotic distribution, and discuss issues of efficiency. We then define instrumental variable (IV) estimators for the regression parameters of the model and give results concerning the joint asymptotic distribution of those estimators and the GM estimator under reasonable conditions. Much of the theory is kept general to cover a wide range of settings. We note the estimation theory developed by Kelejian and Prucha (1998, 1999) for GM and IV estimators and by Lee (2004) for the quasi-maximum likelihood estimator under the assumption of homoskedastic innovations does not carry over to the case of heteroskedastic innovations. The paper also provides a critical discussion of the usual specification of the parameter space.

JEL Code: C21, C31.

Keywords: spatial dependence, heteroskedasticity, Cliff-Ord model, two-stage least squares, generalized moments estimation, asymptotics.

Revised July 2007
1 Introduction

In recent years the economics literature has seen an increasing number of theoretical and applied econometric studies involving spatial issues. While this increase in interest in spatial models in economics is relatively recent, spatial models have a long history in the regional science and geography literature. One of the most widely referenced model of spatial interactions is one that was put forth by Cliff and Ord (1973, 1981). This model is a variant of the model considered by Whittle (1954). In its simplest (and original) form the model only considers spatial spillovers in the dependent variable, and specifies the endogenous variable corresponding to a cross sectional unit in terms of a weighted average of endogenous variables corresponding to other cross sectional units, plus a disturbance term. This model is typically referred to as a spatial autoregressive model, the weighted average is typically referred to as a spatial lag, the corresponding parameter as the autoregressive parameter, and the matrix containing the weights as the spatial weights matrix. A generalized version of this model also allows for the dependent variable to depend on a set of exogenous variables and spatial lags thereof. A further generalization allows for the disturbances to be generated by a spatial autoregressive process. Consistent with the terminology developed by Anselin and Florax (1995) we refer to the combined model as a spatial autoregressive model with autoregressive disturbances of order \((1, 1)\), for short SARAR\((1, 1)\). We note that this model is fairly general in that it allows for spatial spillovers in the endogenous variables, exogenous variables and disturbances.

Somewhat surprisingly, even though the SARAR\((1, 1)\) model has been a modeling tool for many years, until recently there has been a lack of formal results concerning estimation methods for this model. One method that has been employed to estimate this model is the (quasi) maximum likelihood (ML)

---

Also, we gratefully acknowledge financial support from the National Science Foundation through grant SES-0001780 and the National Institute of Health through the SBIR grant 1 R43 AG027622.

procedure, where the likelihood function corresponds to the normal distribution. Formal results concerning the asymptotic properties of the ML estimator have been established only recently in an important contribution by Lee (2004). Given that the likelihood function involves the determinant of a matrix whose dimensions depend on the sample size and an unknown parameter, there can be significant difficulties in the practical computation of this estimator especially if the sample size is large, as it might be if the spatial units relate to counties, single family houses, etc. In part because of this Kelejian and Prucha (1999) introduced a generalized moments (GM) estimator for the autoregressive parameter of the disturbance process that is simple to compute and remains computationally feasible even for large sample sizes. In Kelejian and Prucha (1998) we used that GM estimator to introduce a generalized spatial two stage least squares estimator (GS2SLS) for the regression parameters of the spatial SARAR(1,1) model that is again simple to compute, and demonstrated its consistency and asymptotic normality.4

All of the above estimators for the SARAR(1,1) model were introduced and their asymptotic properties were derived under the assumption that the innovations in the disturbance process are homoskedastic. The lack of an estimation theory that allows for heteroskedasticity, and the lack of corresponding joint hypothesis tests for the presence of spatial dependencies in the endogenous variables, exogenous variables and/or disturbances, is a serious shortcoming. Spatial units are often heterogeneous in important characteristics, e.g., size, and hence the homoskedasticity assumption may not hold in many situations (conditionally and unconditionally). It is readily seen that if the innovations are heteroskedastic, the ML estimator considered in Lee (2004) is inconsistent, and the asymptotic distribution given in Kelejian and Prucha (1998) for the GS2SLS estimator is not appropriate. One important goal of this study is therefore to develop a methodology of inference for the SARAR(1,1) model that allows for heteroskedastic innovations. In developing this theory we will adopt a modular approach such that much of the theory not only applies to the SARAR(1,1) model, but can also be utilized in different settings in future research.

In more detail, in this paper we introduce a new class of GM estimators for the autoregressive parameter of a spatially autoregressive disturbance process that allows for heteroskedastic innovations. Our GM estimators are again computationally simple even in large samples. We determine their consistency; unlike in our earlier paper we also determine, under reasonably general conditions, their asymptotic distribution. Loosely speaking, in deriving those results we essentially only maintain that the disturbances are $n^{1/2}$-consistently estimated (where $n$ is the sample size) and that the estimator of the model parameters employed in estimating the disturbances is asymptotically linear in the innova-

---
4The formulation of the GS2SLS estimator is based on an approximation of the ideal instruments. Recently Lee (2003) and Kelejian, Prucha, and Yuzefovich (2004) extended the analysis to include the use of ideal instruments. Das, Kelejian and Prucha (2003) analyzed the small sample properties of the GS2SLS (as well as those of other estimators). They find that in many situations the loss of efficiency due to the approximation of the ideal instruments is minor.
tions. As a result the methodology developed in this paper covers a wide range of (linear and nonlinear) models and estimators, in addition to the SARAR(1, 1) model and estimators specific for that model. We furthermore derive results concerning the joint distribution of the GM estimators and estimators of the regression parameters to facilitate joint tests. While the results are presented for the case of two step estimation procedures where the spatial autoregressive parameter and the regression parameters are estimated in separate steps, the analysis can be readily adapted to one step procedures where all parameters are estimated in a single (but numerically more involved) step.

The general theory is then applied to develop inference methodology for the SARAR(1, 1) model. In particular, we use the GM estimator in constructing a GS2SLS estimator for the regression parameters of the SARAR(1, 1) model and demonstrate the consistency and asymptotic normality of this estimator. We also provide results concerning the joint distribution of the GM estimator and the GS2SLS estimator, which permits, among other things, testing the joint hypothesis of the absence of spatial spillovers stemming from the endogenous variables, exogenous variables or disturbances.

Another concern with the existing literature on Cliff-Ord type models, including in the above cited literature on the SARAR(1, 1) models, is the specification of the parameter space for spatial autoregressive parameters. In virtually all of the literature it is assumed that the parameter space for autoregressive parameters is the interval (−1, 1), or a subset thereof. One may conjecture that this traditional specification of the parameter space received its motivation from the time series literature. However, as discussed in detail below, choosing the interval (−1, 1) as the parameter space for the autoregressive parameter of a spatial model is not natural in the sense that the spatial autoregressive parameter always appears in those models in product form with the spatial weights matrix. Hence equivalent model formulations are obtained by applying an (arbitrary) scale factor to the autoregressive parameter and its inverse to the weights matrix. Of course, applying a scale factor to the autoregressive parameter leads to a corresponding re-scaling of its parameter space. In this paper we therefore allow for a more general specification of the parameter space. Even if a scale factor is used that results in the parameter space being the interval (−1, 1), this scale factor and correspondingly the autoregressive parameter will then typically depend on the sample size. In contrast to the existing literature we thus allow for the parameters to depend on the sample size. Our discussion of the parameter space and possible normalizations of the spatial weights matrix also points out potential pitfalls with the frequently used approach of row-normalizing the spatial weights matrix.

The paper is organized as follows: The generalized SARAR(1, 1) model is specified and interpreted in Section 2. This section also contains a discussion of the parameter space of the autoregressive parameter. In Section 3 we define and establish the large sample properties of our suggested GM estimators for the autoregressive parameter of a spatially autoregressive disturbance process. In this section we also provide results concerning the joint large sample distribution of the GM estimators and a wide class of estimator of the regression parameters.
We also develop HAC type estimators for the large sample variance-covariance matrix of the suggested estimators. Section 4 contains results relating to the suggested instrumental variable estimators of the regression parameters of the SARAR(1,1) model and their joint large sample distribution with GM estimators. Concluding remarks are given in the Section 5. Technical details are relegated to the appendices.

It proves helpful to introduce the following notation: Let $A_n$ with $n \in \mathbb{N}$ be some matrix; we then denote the $(i,j)$-th element of $A_n$ as $a_{ij,n}$. Similarly, if $v_n$ is a vector, then $v_{i,n}$ denotes the $i$-th element of $v_n$. An analogous convention is adopted for matrices and vectors that do not depend on the index $n$, in which case the index $n$ is suppressed on the elements. If $A_n$ is a square matrix, then $A_n^{-1}$ denotes the inverse of $A_n$. If $A_n$ is singular, then $A_n^{-1}$ should be interpreted as the generalized inverse of $A_n$. At times it will also be helpful to denote the generalized inverse more explicitly as $A_n^+$. With $a_{i,n}$ and $a_{i,n}$ we denote the $i$-th row and column of $A_n$, respectively, and with $a_{i,n}^+$ and $a_{i,n}^+$ those of $A_n^{-1}$. If $A_n$ is a square symmetric nonnegative matrix, then $A_n^{1/2}$ denotes the unique symmetric and nonnegative square root of $A_n$. If $A_n$ is nonsingular, then $A_n^{-1/2}$ denotes $(A_n^{-1})^{1/2}$. Further, we say the row and column sums of the (sequence of) matrices $A_n$ are bounded uniformly in absolute value if there exists a constant $c_A < \infty$ (that does not dependent of $n$) such that

$$
\max_{1 \leq i \leq n} \sum_{j=1}^{n} |a_{ij,n}| \leq c_A \quad \text{and} \quad \max_{1 \leq j \leq n} \sum_{i=1}^{n} |a_{ij,n}| \leq c_A \quad \text{for all } n \in \mathbb{N}
$$

holds. As a point of interest, we note that the above condition is identical to the condition that the sequences of the maximum column sum matrix norms and maximum row sum matrix norms of $A_n$ are bounded; cp. Horn and Johnson (1985, pp.294-5). For definiteness, let $A$ be some vector or matrix, then $\|A\| = [\text{Tr}(A^t A)]^{1/2}$. We note that this norm is submultiplicative, i.e., $\|AB\| \leq \|A\| \|B\|$.

2 Model

In this section we specify the generalized SARAR(1,1) model and discuss the underlying assumptions.

2.1 Specification

Suppose a cross section of $n$ spatial units is observed, and the interactions between those spatial units can be described by the following model:

$$
y_n = X_n \beta_n + \lambda_n W_n y_n + u_n
$$

and

$$
u_n = \rho_n M_n u_n + \varepsilon_n,
$$

(1)
with $\mathbf{Z}_n = [\mathbf{X}_n, \mathbf{W}_n, \mathbf{y}]$ and $\mathbf{\delta}_n = [\mathbf{\beta}'_n, \lambda_n]'$. Here $\mathbf{y}_n$ denotes the $n \times 1$ vector of observations of the dependent variable, $\mathbf{X}_n$ denotes the $n \times k$ matrix of non-stochastic (exogenous) regressors, $\mathbf{W}_n$ and $\mathbf{M}_n$ are $n \times n$ non-stochastic matrices, $\mathbf{u}_n$ denotes the $n \times 1$ vector of innovations, $\lambda_n$ and $\rho_n$ are unknown scalar parameters, and $\mathbf{\beta}_n$ is a $k \times 1$ vector of unknown parameters. The matrices $\mathbf{W}_n$ and $\mathbf{M}_n$ are typically referred to as spatial weights matrices, and $\lambda_n$ and $\rho_n$ are typically called spatial autoregressive parameters. The analysis allows for $\mathbf{W}_n = \mathbf{M}_n$, which will frequently be the case in applications. All quantities are allowed to depend on the sample size.

The vectors $\mathbf{y}_n = \mathbf{W}_n \mathbf{y}_n$ and $\mathbf{u}_n = \mathbf{M}_n \mathbf{u}_n$ are typically referred to as spatial lags of $\mathbf{y}_n$ and $\mathbf{u}_n$, respectively. We note that all quantities are allowed to depend on the sample size and so some of the exogenous regressors may be spatial lags of exogenous variables. Thus the model is fairly general in that it allows for spatial spillovers in the endogenous variables, exogenous variables and disturbances.

The spatial weights matrices and the autoregressive parameters are assumed to satisfy the following assumption.

**Assumption 1** (a) All diagonal elements of $\mathbf{W}_n$ and $\mathbf{M}_n$ are zero. (b) $\lambda_n \in (-\infty, \lambda_n^*)$, $\rho_n \in (-\infty, \rho_n^*)$ with $0 < \lambda_n^* \leq \lambda_n < \infty$ and $0 < \rho_n^* \leq \rho_n < \infty$. (c) The matrices $\mathbf{I}_n - \lambda \mathbf{W}_n$ and $\mathbf{I}_n - \rho \mathbf{M}_n$ are nonsingular for all $\lambda \in (-\lambda_n^*, \lambda_n^*)$, and $\rho \in (-\rho_n^*, \rho_n^*)$.

Assumption 1(a) is clearly a normalization rule. Assumption 1(b) concerning the parameter space of $\lambda_n$ and $\rho_n$ will be discussed in the next subsection. Assumption 1(c) ensures that $\mathbf{y}_n$ and $\mathbf{u}_n$ are uniquely defined by (1) and (2) as

\[
\begin{align*}
\mathbf{y}_n & = (\mathbf{I}_n - \lambda_n \mathbf{W}_n)^{-1} \mathbf{X}_n \mathbf{\beta}_n + (\mathbf{I}_n - \lambda_n \mathbf{W}_n)^{-1} \mathbf{u}_n, \\
\mathbf{u}_n & = (\mathbf{I}_n - \rho_n \mathbf{M}_n)^{-1} \mathbf{\varepsilon}_n. 
\end{align*}
\]

As remarked in the Introduction, spatial units are often heterogeneous in important characteristics, e.g., size. For that reason it is important to develop an estimation theory that allows for the innovations to be heteroskedastic. Therefore, we maintain the following set of assumptions with respect to the innovations.

**Assumption 2** The innovations $\{\mathbf{\varepsilon}_{i,n} : 1 \leq i \leq n, n \geq 1\}$ satisfy $E \mathbf{\varepsilon}_{i,n} = 0$, $E(\mathbf{\varepsilon}_{i,n}^2) = \sigma_i^2$ with $0 < \sigma_i^2 \leq \sigma^* \leq \infty$, and $\sup_{1 \leq i \leq n, n \geq 1} E|\mathbf{\varepsilon}_{i,n}|^{4+\eta} < \infty$ for some $\eta > 0$. Furthermore, for each $n \geq 1$ the random variables $\mathbf{\varepsilon}_{1,n}, \ldots, \mathbf{\varepsilon}_{n,n}$ are totally independent.

The above assumption also allows for the innovations to depend on the sample size $n$, i.e., to form triangular arrays. We note that even if the innovations do not depend on $n$, the elements of $\mathbf{y}_n$ and $\mathbf{u}_n$ would still depend on $n$ in light of (3) since the elements of the inverse matrices involved would generally depend on $n$. We maintain the following assumption concerning the spatial weights matrices.
Assumption 3 The row and column sums of the matrices $W_n$, $M_n$, $(I_n - \lambda_n W_n)^{-1}$ and $(I_n - \rho_n M_n)^{-1}$ are bounded uniformly in absolute value.

Given (3), Assumption 2 implies that $E u_n = 0$, and that the VC matrix of $u_n$ is given by

$$E u_n u_n' = (I_n - \rho_n M_n)^{-1} \Sigma_n (I_n - \rho_n M_n)^{-1}$$

where $\Sigma_n = \text{diag}(\sigma_{i,n}^2)$. This specification allows for fairly general patterns of autocorrelation and heteroskedasticity of the disturbances. It is readily seen that the row and column sums of products of matrices, whose row and column sums are bounded uniformly in absolute value, are again uniformly bounded in absolute value; see, e.g., Kelejian and Prucha (2004), Remark A.1. Because of this, Assumptions 2 and 3 imply that the row and column sums of the variance-covariance (VC) matrix of $u_n$ (and similarly those of $y_n$) are uniformly bounded in absolute value, thus limiting the degree of correlation between, respectively, the elements of $u_n$ (and of $y_n$). That is, making an analogy to the time series literature, these assumptions ensure that the disturbance process and the process for the dependent variable exhibit a “fading” memory.5

2.2 Parameter Space for an Autoregressive Parameter

Assumption 1(b) defines the parameter space for the autoregressive parameters. In discussing this assumption we focus on $W_n$ and $\lambda_n$. (An analogous discussion applies to $M_n$ and $\rho_n$.) In the existing literature relating to Cliff-Ord models the parameter space for the autoregressive parameter is typically taken to be the interval $(-1, 1)$ and the autoregressive parameter is assumed not to depend on the sample size. However, in applications it is typically found that for unnormalized spatial weights matrices, $I_n - \lambda_n W_n$ is singular for some values of $\lambda \in (-1, 1)$. To avoid this situation, many applied researchers normalize each row of their spatial weights matrices in such a way that $I_n - \lambda_n W_n$ is non-singular for all $\lambda \in (-1, 1)$. We now discuss the implications of various normalizations of the spatial weight matrix.

Suppose $c_n$ denotes a scalar normalization factor. Clearly, this normalization factor may depend on the sample size. For example, some of our results below relate to the case in which $c_n$ corresponds to the maximal row or column sum of the absolute values of the elements of $W_n$. Given such a normalizing factor, an equivalent specification of model (1) for $y_n$ is obtained if $\lambda_n W_n$ is replaced by $\lambda_n^* W_n^*$, where $\lambda_n^* = c_n \lambda_n$ and $W_n^* = W_n/c_n$. It is important to observe that even if $\lambda_n$ and its corresponding parameter space do not depend on $n$, $\lambda_n^*$ and its implied parameter space will depend on the sample size as a result of the normalization of the spatial weights matrix.6 It is for this reason that we allow in Assumption 1 for the elements of the spatial weights matrices, and the

5 Of course, the extent of correlation is limited in virtually all large sample analysis; see, e.g., Amemiya (1985), ch. 3,4, and Pötscher and Prucha (1997), ch. 5,6.

6 The parameter space for $\lambda_n^*$ is given by $(-c_n \lambda_n^*, c_n \lambda_n^*)$. 

7
autoregressive parameters and the corresponding parameter spaces to depend on \( n \). Of course, Assumption 1 also covers the case where the true data generating process corresponds to a model where autoregressive parameters do not depend on \( n \).

Assumption 1 defines the parameter space for \( \lambda_n \) as an interval around zero such that \( \mathbf{I}_n - \lambda \mathbf{W}_n \) is nonsingular for values \( \lambda \) in that interval. The following trivial lemma gives bounds for that interval.

**Lemma 1** Let \( \tau_n \) denote the spectral radius of \( \mathbf{W}_n \); i.e.,

\[
\tau_n = \max \{ |\nu_{1,n}|, \ldots, |\nu_{n,n}| \}
\]

where \( \nu_{1,n}, \ldots, \nu_{n,n} \) denote the eigenvalues of \( \mathbf{W}_n \). Then \( \mathbf{I}_n - \lambda \mathbf{W}_n \) is nonsingular for all values of \( \lambda \) in the interval \((-1/\tau_n, 1/\tau_n)\).

Clearly, if we select \((-1/\tau_n, 1/\tau_n)\) as the parameter space for \( \lambda_n \), then all eigenvalues of \( \lambda_n \mathbf{W}_n \) are less than one in absolute value. Thus if we interpret (1) as an equilibrium relationship, then this choice of the parameter space rules out unstable Nash equilibria. Of course, we obtain an equivalent specification of the model if instead of working with \( \mathbf{W}_n \) we work with the normalized weights matrix \( \mathbf{W}_n^* = \mathbf{W}_n / \tau_n \) and select the interval \((-1, 1)\) as the parameter space for \( \lambda_n^* = \lambda_n \tau_n \). Assumption 1 is sufficiently general to cover both cases.

For large sample sizes the computation of the eigenvalues on \( \mathbf{W}_n \) is difficult. The following lemma gives boundaries, which are simple to compute, for a (sub)set of values of \( \lambda \) for which \( \mathbf{I}_n - \lambda \mathbf{W}_n \) is nonsingular.

**Lemma 2** Let

\[
\tau_n^* = \min \{ \max_{1 \leq i \leq n} \sum_{j=1}^{n} |w_{ij,n}|, \max_{1 \leq j \leq n} \sum_{i=1}^{n} |w_{ij,n}| \}
\]

Then \( \tau_n \leq \tau_n^* \) and consequently \( \mathbf{I}_n - \lambda \mathbf{W}_n \) is nonsingular for all values of \( \lambda \) in the interval \((-1/\tau_n^*, 1/\tau_n^*)\).

The above lemma suggests \((-1/\tau_n^*, 1/\tau_n^*)\) as an alternative (although somewhat more restrictive) specification of the parameter space. Of course, we obtain an equivalent model specification if we normalize the spatial weights matrix by \( \tau_n^* \) and if we choose \((-1, 1)\) as the parameter space for the autoregressive parameter. Since the spectral radius is bound by any matrix norm, other norms in place of the maximum absolute row and column sum norms can be used, but \( \tau_n^* \) is especially easy to compute.

Rather than to normalize \( \mathbf{W}_n \) by \( \tau_n \) or \( \tau_n^* \), in much of the empirical literature the spatial weights matrices are normalized such that each row sums to unity.

---

7 In some of the spatial literature the following closely related claim can be found: \( \mathbf{I}_n - \lambda \mathbf{W}_n \) is nonsingular for all values of \( \lambda \) in the interval \((1/\nu_n, \min, 1/\nu_n, \max)\), where \( \nu_n, \min \) and \( \nu_n, \max \) denote the smallest and largest eigenvalue of \( \mathbf{W}_n \), respectively. This claim is correct for the case in which all eigenvalues of \( \mathbf{W}_n \) are real and \( \nu_n, \min < 0 \) and \( \nu_n, \max > 0 \). Since, e.g., the eigenvalues of \( \mathbf{W}_n \) need not be real, this claim does not hold in general.
The motivation for this normalization is that if $W_n$ is row-normalized then $I_n - \lambda W_n$ is nonsingular for all values of $\lambda$ in the interval $(-1, 1)$; this can be readily confirmed via Lemma 2. However, this normalization is quite different than those described above in that in row-normalizing a matrix one does not use a single normalization factor, but rather a different factor for the elements of each row. Therefore, in general, there exists no corresponding re-scaling factor for the autoregressive parameter that would lead to a specification that is equivalent to that corresponding to the un-normalized weights matrix. Consequently, unless theoretical issues suggest a row-normalized weights matrix, this approach will in general lead to a misspecified model.

The above discussion provides the motivation for our specification that the autoregressive parameters may depend on $n$. Furthermore, since some of the regressors may be spatial lags, we allow all of the model parameters to depend on the sample size.

3 GM Estimator for the Autoregressive Parameter $\rho_n$

In the following we introduce a class of GM estimators for $\rho_n$ that can be easily computed, and prove their consistency and asymptotic normality under a set of general assumptions. We note that the discussion in this section only maintains model (2) for the disturbances $u_n$, but not necessarily (1) for $y_n$. Thus the results will also be useful in other settings such as cases where $y_n$ is determined by a nonlinear model; see, e.g. Kelejian and Prucha (2001, p. 228). The estimators put forth below generalize the GM estimator for $\rho_n$ introduced in Kelejian and Prucha (1999). In contrast to that earlier paper we now allow for heteroskedastic innovations $\varepsilon_{i,n}$, and optimal weighting of the moment conditions. We also do not confine the parameter space for $\rho_n$ to be the interval $(-1, 1)$, and allow $\rho_n$ to depend on $n$. In our earlier paper we only demonstrated the consistency of the estimator. In the following we also derive the asymptotic distribution of the considered estimators.

3.1 Definition of the GM Estimator for $\rho_n$

In the following let $\tilde{u}_n$ denote some predictor of $u_n$. Furthermore, for notational convenience let $\mathbf{u}_n = M_n u_n$ and $\mathbf{v}_n = M_n u_n = M_n^2 u_n$, and correspondingly, $\tilde{u}_n = M_n \tilde{u}_n$, and $\tilde{v}_n = M_n^2 \tilde{u}_n$. Similarly, let $z_n = M_n \varepsilon_n$. It is readily seen that under Assumptions 1 and 2 we have the following moment conditions:

$$n^{-1} E z_n' \varepsilon_n = n^{-1} \text{Tr} \{ N_n \left[ diag_{i=1}^n (E \varepsilon_{i,n}^2) \right] N_n' \}, \quad (4)$$

$$n^{-1} E \varepsilon_n' \varepsilon_n = 0.$$  

It proves convenient to rewrite these conditions as

$$n^{-1} E \begin{bmatrix} \varepsilon_n' A_{1,n} \varepsilon_n \\
\varepsilon_n' A_{2,n} \varepsilon_n \end{bmatrix} = 0 \quad (5)$$
with  
\[ A_{1,n} = M_n' M_n - \text{diag}_{i=1}^n (m_{i,n}'), \quad A_{2,n} = M_n. \]

Under Assumptions 1 and 3 it is readily seen that the diagonal elements of \( A_{1,n} \) and \( A_{2,n} \) are zero and that the row and column sums of \( A_{1,n} \) and \( A_{2,n} \) are bounded uniformly in absolute value; see, e.g., Remark A.1 in Kelejian and Prucha (2004).

Our GM estimators for \( \rho_n \) are based on these moments. Specifically, note that in light of (2) \( \varepsilon_n = (I_n - \rho_n \bar{M}_n) u_n = u_n - \rho_n \bar{u}_n \) and so \( \varepsilon_n = \bar{u}_n - \rho_n \bar{u}_n \). Substituting these expressions into (4) or (5) yields the following two equation system:

\[ \gamma_n - \Gamma_n \alpha_n = 0 \]  
(6)

where \( \alpha_n = [\rho_n, \rho_n^2]' \) and the elements of \( \Gamma_n = [\gamma_{rs,n}]_{r,s=1,2} \) and \( \gamma_n = [\gamma_{1,n}, \gamma_{2,n}]' \) are given by

\[ \gamma_{11,n} = 2n^{-1} E \left\{ \bar{u}_n' \bar{u}_n - Tr \left[ M_n \left[ \text{diag}_{i=1}^n (\bar{u}_{i,n}) \right] M_n' \right] \right\} \]
\[ = 2n^{-1} E u_n' M_n' A_{1,n} u_n, \]
\[ \gamma_{12,n} = -n^{-1} E \left\{ \bar{u}_n' \bar{u}_n + Tr \left[ M_n \left[ \text{diag}_{i=1}^n (\bar{u}_{i,n}^2) \right] M_n' \right] \right\} \]
\[ = -n^{-1} E u_n' M_n' A_{1,2,n} u_n, \]
\[ \gamma_{21,n} = n^{-1} E \left( u_n' \bar{u}_n + \bar{u}_n' u_n \right) \]
\[ = n^{-1} E u_n' M_n' (A_{2,n} + A_{2,2,n}) u_n, \]
\[ \gamma_{22,n} = -n^{-1} E \bar{u}_n' \bar{u}_n \]
\[ = -n^{-1} E u_n' M_n' A_{2,2,n} u_n, \]
\[ \gamma_{11,n} = n^{-1} E \left\{ \bar{u}_n' \bar{u}_n - Tr \left[ M_n \left[ \text{diag}_{i=1}^n (u_{i,n}^2) \right] M_n' \right] \right\} \]
\[ = -n^{-1} E u_n' A_{1,1,n} u_n, \]
\[ \gamma_{22,n} = n^{-1} E \bar{u}_n' \bar{u}_n \]
\[ = n^{-1} E u_n' A_{2,2,n} u_n. \]

Now let \( \bar{\gamma}_n = [\bar{\gamma}_{1,n}^0, \bar{\gamma}_{2,n}^0]' \) and \( \bar{\gamma}_n = [\bar{\gamma}_{1,n}, \bar{\gamma}_{2,n}]' \) denote corresponding estimators for the elements of \( \Gamma_n \) and \( \gamma_n \), which are obtained from the above expressions for the elements of \( \Gamma_n \) and \( \gamma_n \) by suppressing the expectations operator, and replacing the disturbances \( u_n, \bar{u}_n, \text{ and } \bar{u}_n \) by their predictors \( \bar{u}_n, \bar{u}_n, \text{ and } \bar{u}_n \), respectively. Then, the empirical analog of the relationship in (6) is

\[ \bar{\gamma}_n - \bar{\Gamma}_n \alpha_n = \varepsilon_n, \]  
(8)

where \( \varepsilon_n \) can be viewed as a vector of regression residuals. Our GM estimators of \( \rho_n \), say \( \bar{\rho}_n \), are now defined as weighted nonlinear least squares estimators based on (8). That is, let \( \bar{\gamma}_n \) be a \( 2 \times 2 \) symmetric positive semidefinite (moments) weighting matrix; then \( \bar{\rho}_n \) is defined as
\[ \tilde{\rho}_n = \rho_n(\bar{Y}_n) = \arg\min_{\rho \in [-a^\rho, a^\rho]} \left\{ \left[ \bar{\gamma}_n - \bar{\Gamma}_n \begin{bmatrix} \rho^2 \\ \rho^2 \end{bmatrix} \right]' \bar{Y}_n \left[ \bar{\gamma}_n - \bar{\Gamma}_n \begin{bmatrix} \rho^2 \\ \rho^2 \end{bmatrix} \right] \right\}. \quad (9) \]

We note that the objective function for \( \tilde{\rho}_n \) remains well defined even for values of \( \rho_n \) for which \( I_n - \rho_n M_n \) is singular, which allows us to take the optimization space for \( \tilde{\rho}_n \) to be any compact interval that contains the true parameter space.

For computational efficiency it is best to use the formulae for the elements of \( \bar{\gamma}_n \) and \( \bar{\Gamma}_n \) corresponding to the first expression on the r.h.s. of (7) and to compute \( \bar{u}_n \) and \( \bar{v}_n \) recursively as \( \bar{u}_n = M_n \bar{u}_n \) and \( \bar{v}_n = M_n \bar{v}_n \). In this fashion one can avoid the computation of \( M_n^2 \), i.e., the computation of the product of two \( n \times n \) matrices.

We now relate the above estimator for the autoregressive parameter to the GM estimator introduced in Kelejian and Prucha (1999). Under homoskedasticity, \( \sigma^2 = \sigma_i^2 \) and so \( E[n^{-1} \varepsilon_n' \varepsilon_n] = \sigma^2 \), \( E[n^{-1} \varepsilon_n' \varepsilon_n] = \sigma^2 n^{-1} Tr \{M_n M'_n\} \), and \( E[n^{-1} \varepsilon_n' \varepsilon_n] = 0 \). These three moment conditions underlie the GM estimator suggested in Kelejian and Prucha (1999). Substituting the first of these moment conditions into the second yields

\[ E[n^{-1} \varepsilon_n' \varepsilon_n] = E[n^{-1} \varepsilon_n' \varepsilon_n] n^{-1} Tr \{M_n M'_n\}, \quad (10) \]

which is clearly a special case of (4) under homoskedasticity. It is not difficult to see that the GM estimator suggested in our previous paper can be viewed as being based on the two moment conditions in (10) with \( \bar{Y}_n = \text{diag}(v_n, 1) \) and \( v_n = 1/ \left[ 1 + \left( n^{-1} Tr \{M_n M'_n\} \right)^2 \right] \).

3.2 Consistency of the GM Estimator for \( \rho_n \)

To establish consistency of \( \tilde{\rho}_n \) we postulate the following additional assumptions.

**Assumption 4**: Let \( \tilde{u}_{i,n} \) denote the \( i \)-th element of \( \tilde{u}_n \). We then assume that

\[ \tilde{u}_{i,n} - u_{i,n} = d_{i,n} \Delta_n \]

where \( d_{i,n} \) and \( \Delta_n \) are \( 1 \times p \) and \( p \times 1 \) dimensional random vectors. Let \( d_{ij,n} \) be the \( j \)-th element of \( d_{i,n} \). Then, we assume that for some \( \delta > 0 \) \( E |d_{ij,n}|^{2+\delta} \leq c_d < \infty \) where \( c_d \) does not depend on \( n \), and that \( n^{1/2} \| \Delta_n \| = O_p(1) \).

---

*If we rewrite the moment conditions in (10) in the form corresponding to (5), then \( A_{1,n} = M_n' M_n - n^{-1} Tr \{M_n M'_n\} I_n \) and \( A_{2,n} = M_n \).*
Assumption 5  (a) The smallest eigenvalue of $\Gamma_n' \Gamma_n$ is uniformly bounded away from zero.\(^9\) (b) $\tilde{\Upsilon}_n - \Upsilon_n = o_p(1)$, where $\Upsilon_n$ are $2 \times 2$ non-stochastic symmetric positive definite matrices. (c) The largest eigenvalues of $\Upsilon_n$ are bounded uniformly from above, and the smallest eigenvalues of $\Upsilon_n$ are uniformly bounded away from zero.

Assumption 4 implies $n^{-1} \sum_{i=1}^{n} \|d_{i,n}\|^{2+\delta} = O_p(1)$, which was maintained in Kelejian and Prucha (1999), and so is slightly stronger than their assumption. Assumption 4 should be satisfied for typical linear spatial models where $\tilde{u}_i$ is based on $n^{1/2}$-consistent estimators of regression coefficients, $d_{i,n}$ denotes the $i$-th row of the regressor matrix, and $\Delta_n$ denotes the difference between the parameter estimator and the true parameter values. In the next section we will actually demonstrate that Assumption 4 holds for the estimated residuals of model (1) based on an instrumental variable procedure. Assumption 4 should also be satisfied for typical non-linear models provided the response function is differentiable in the parameters, and the derivatives are (uniformly over the parameter space) bounded by some random variable with bounded $2+\delta$ moments; compare Kelejian and Prucha (1999).

Assumption 5 ensures that the smallest eigenvalue of $\Gamma_n' \Upsilon_n \Gamma_n$ is uniformly bounded away from zero and will be sufficient to permit us to demonstrate that $\rho_n$ is identifiably unique w.r.t. the nonstochastic analogue of the objective function of the GM estimator. This analogue is given by the function in curly brackets on the r.h.s. of (9) with $\tilde{\gamma}_n, \tilde{\Gamma}_n$ and $\tilde{\Upsilon}_n$ replaced by $\gamma_n, \Gamma_n$ and $\Upsilon_n$. Under homoskedasticity and $\tilde{\Upsilon}_n = \Upsilon_n$ specified as at the end of the previous subsection this assumption is in essence equivalent to Assumption 5 in Kelejian and Prucha (1999).

Clearly Assumption 5 requires $\Gamma_n$ to be nonsingular, or equivalently that $\{tr(M_n'A_{1,n}M_nS_{u,n}), tr(M_n'A_{2,n}M_nS_{u,n})\}$ is linearly independent of $\{tr(M_n(A_{1,n} + A_{1,n}')S_{u,n}), tr(M_n'(A_{2,n} + A_{2,n}')S_{u,n})\}$, which is readily seen by observing that $Eu_n' M_n' A_{1,n} M_n u_n = tr(M_n' A_{1,n} M_n S_{u,n})$ and $n^{-1} Eu_n' M_n'(A_{1,n} + A_{1,n}')u_n = tr(M_n' (A_{1,n} + A_{1,n}') S_{u,n})$ where $S_{u,n} = (I_n - \rho_n M_n)^{-1} \Sigma_n(I_n - \rho_n M_n)^{-1}$. It is not difficult to see that this linear independence condition is an analogue to identification conditions postulated in Lee (2007), Assumption 5(b), relating to quadratic forms under homoskedasticity.

We note that while Assumption 5 should be satisfied in many settings, it does not cover situations where all elements of the spatial weights matrix converge to zero uniformly as $n \to \infty$ - see Lee (2004) - since in this case the elements of $\Gamma_n$ would tend to zero. On the other hand, Assumption 5 does not generally

\[^9\] That is, $\lambda_{\min}(\Gamma_n' \Gamma_n) \geq \lambda_\gamma > 0$ where $\lambda_\gamma$ does not depend on $n$. More specifically, in general $\Gamma_n$ depends on $M_n, \rho_n, \sigma_{1,n}^2, \ldots, \sigma_{2,n}^2$. Denoting this dependence as $\Gamma_n = \Gamma_n(M_n, \rho_n, \sigma_{1,n}^2, \ldots, \sigma_{2,n}^2)$ the assumption should be understood as to postulate that

$$\inf_n \lambda_{\min} [\Gamma_n(M_n, \rho_n, \sigma_{1,n}^2, \ldots, \sigma_{2,n}^2) \Gamma_n(M_n, \rho_n, \sigma_{1,n}^2, \ldots, \sigma_{2,n}^2)] > 0.$$ 

In this sense the assumption allows for $\lambda_\gamma$ to depend on the sequence of spatial weights matrices $M_n$, and on the true values of the autoregressive parameters $\rho_n$ and variances.
rule out settings where \( M_n \) is row normalized, there is an increasing number of nonzero elements in each row, and the row sums of the absolute values of the non-normalized elements are uniformly bounded.

The vector of derivatives (multiplied by minus one) of the moment conditions (6) w.r.t. \( \rho_n \) is given by \( J_n = \Gamma_n[1,2\rho_n]' \). As expected, the limiting distribution of the GM estimator \( \rho_n \) will be seen to depend on the inverse of \( J_n' \Upsilon_n J_n \). Assumption 5 also ensure that \( J_n' \Upsilon_n J_n \) is nonsingular.

Because of the equivalence of matrix norms it follows from Assumption 5 that the elements of \( \Upsilon_n \) and \( \Upsilon_n^{-1} \) are \( O(1) \).

We can now give our basic consistency result for \( \rho_n \).

**Theorem 1** Let \( \tilde{\rho}_n = \tilde{\rho}_n(\tilde{\Upsilon}_n) \) denote the GM estimator defined by (9). Then, provided the optimization space contains the parameter space, and given Assumptions 1-5,

\[
\tilde{\rho}_n - \rho_n \overset{P}{\to} 0 \quad \text{as } n \to \infty.
\]

Clearly the conditions of the theorem regarding \( \tilde{\Upsilon}_n \) and \( \Upsilon_n \) are satisfied for \( \tilde{\Upsilon}_n = \Upsilon_n = I_2 \). In this case the estimator reduces to the nonlinear least squares estimator based on (8). This estimator can, e.g., be used to obtain initial consistent estimates of the autoregressive parameter. Choices of \( \tilde{\Upsilon}_n \) that lead to an efficient GM estimator for \( \rho_n \) (but require some consistent initial estimate of \( \rho_n \)) will be discussed below in conjunction with the asymptotic normality result.

### 3.3 Asymptotic Distribution of the GM Estimator for \( \rho_n \)

Let \( D_n = [d_{i,n}, \ldots, d_{n,n}]' \) where \( d_{i,n} \) is defined in Assumption 4 so that \( \tilde{u}_n - u_n = D_n \Delta_n \). To establish the asymptotic normality of \( \tilde{\rho}_n \) we need some additional assumptions.

**Assumption 6** For any \( n \times n \) real matrix \( A_n \) whose row and column sums are bounded uniformly in absolute value

\[
n^{-1}D_n'A_n u_n - n^{-1}E D_n'A_n u_n = o_p(1).
\]

A sufficient condition for Assumption 6 is, e.g., that the columns of \( D_n \) are of the form \( \pi_n + \Pi_n \varepsilon_n \), where the elements of \( \pi_n \) are bounded in absolute value and the row and column sums of \( \Pi_n \) are uniformly bounded in absolute value; see Lemma C.2. This will indeed be the case in many applications. In the next section we will verify that this assumption holds for the model given by (1) and (2), and where \( D_n \) equals the (negative of the) design matrix \( Z_n \).

**Assumption 7** Let \( \Delta_n \) be as defined in Assumption 4. Then

\[
n^{1/2} \Delta_n = n^{-1/2}T_n' \varepsilon_n + o_p(1),
\]

where \( T_n \) is a \( n \times p \) dimensional real nonstochastic matrix whose elements are uniformly bounded in absolute value.
As remarked above, typically $\Delta_n$ denotes the difference between the parameter estimator and the true parameter values. Assumption 7 will be satisfied by many estimators. In the next section we verify that this assumption indeed holds for the considered instrumental variable estimators for the parameters of model (1).

It may be helpful to provide some insight concerning the variance of the limiting distribution of the GM estimator $n^{1/2}(\tilde{\rho}_n - \rho_n)$ given below. To that effect we note that an inspection of the derivation of this limiting distribution in Appendix C shows that it depends on the limiting distribution of the (properly normalized) vector of quadratic forms

$$v_n = n^{-1/2} \left[ \frac{1}{\tau_n} (A_{1,n} + A'_{1,n}) \varepsilon_n + \alpha_{1,n} \varepsilon_n \right]$$

where for $r = 1, 2$ the $n \times n$ matrices $A_{r,n}$ are defined in (5), and where the $n \times 1$ vectors $\alpha_{r,n}$ are defined as

$$\alpha_{r,n} = T_n \alpha_{r,n}$$

with

$$\alpha_{r,n} = n^{-1} E \left[ D_n' (I_n - \rho_n M_n) (A_{r,n} + A'_{r,n}) (I_n - \rho_n M_n) u_n \right].$$

From (11) and (12) we see that, in general, the limiting distribution of $n^{1/2}(\tilde{\rho}_n - \rho_n)$ will depend on the limiting distribution of $n^{1/2} \Delta_n$ via the matrix $T_n$, unless $\alpha_{r,n} = 0$. Clearly, if $D_n$ is not stochastic, then $\alpha_{r,n} = 0$. Within the the context of model (1) and with $D_n$ equal to the (negative of the) design matrix $Z_n$ this would be the case if the model does not contain a spatial lag of the endogenous variable.

Observing further that the diagonal elements of the matrices $A_{r,n}$ are zero it follows from Lemma A.1 that the VC matrix of the vector of quadratic forms in (11) is given by $\Psi_n = (\psi_{rs,n})$ where for $r, s = 1, 2$

$$\psi_{rs,n} = (2n)^{-1} tr \left[ (A_{r,n} + A'_{r,n}) \Sigma_n (A_{s,n} + A'_{s,n}) \Sigma_n \right] + n^{-1} a'_{r,n} \Sigma_n a_{s,n}. \quad (13)$$

We now have the following result concerning the asymptotic distribution of $\tilde{\rho}_n$. We note that the theorem does not assume convergence of the matrices involved.

**Theorem 2** (Asymptotic normality) Let $\tilde{\rho}_n$ be the weighted nonlinear least squares estimators defined by (9). Then, provided the optimization space contains the parameter space, given Assumptions 1-7, and given that $\lambda_{\min}(\Psi_n) \geq c_\Phi > 0$, we have

$$n^{1/2}(\tilde{\rho}_n - \rho_n) = (J_n' \Upsilon_n J_n)^{-1} J_n' \Upsilon_n \Psi_n^{1/2} \xi_n + o_p(1) \quad (14)$$

where

$$J_n = \Upsilon_n \begin{bmatrix} 1 \\ 2\rho_n \end{bmatrix},$$

$$\xi_n = \Psi_n^{-1/2} v_n \frac{\delta_n}{\sqrt{n}} \sim N(0, I_2)$$

14
Furthermore \( n^{1/2}(\hat{\rho}_n - \rho_n) = O_p(1) \) and
\[
\Omega_{\hat{\rho}_n}(Y_n) = (J_n'Y_nJ_n)^{-1}J_n'Y_n\Psi_nY_nJ_n(J_n'Y_nJ_n)^{-1} \geq \text{const} > 0. \tag{16}
\]

The above theorem implies that the difference between the cumulative distribution function of \( n^{1/2}(\hat{\rho}_n - \rho_n) \) and that of \( N[0, \Omega_{\hat{\rho}_n}] \) converges pointwise to zero, which justifies the use of the latter distribution as an approximation of the former.\(^{10}\)

Remark 1. Clearly \( \Omega_{\hat{\rho}_n}(\Psi_n^{-1}) = (J_n'\Psi_n^{-1}J_n)^{-1} \) and \( \Omega_{\hat{\rho}_n}(Y_n) - \Omega_{\hat{\rho}_n}(\Psi_n^{-1}) \) is positive semi-definite. Thus choosing \( Y_n \) as a consistent estimator for \( \Psi_n^{-1} \) leads to the efficient GM estimator. Such a consistent estimator will be developed in the next subsection. As discussed in the proof of the above theorem, the elements of \( \Psi_n \) are uniformly bounded in absolute value and hence \( \lambda_{\text{max}}(\Psi_n) \leq c_{\Psi}^* \) for some \( c_{\Psi}^* < \infty \). Since by assumption also \( 0 < c_{\Psi} \leq \lambda_{\min}(\Psi_n) \) it follows that the conditions on the eigenvalues of \( Y_n \) postulated in Assumption 5 are automatically satisfied by \( \Psi_n^{-1} \). We note that \( \Psi_n \) is, in general, only identical to the VC matrix of the moment vector in (5) if \( a_{r,n} = 0 \). The terms involving \( a_{r,n} \) reflect the fact that the GM estimator is based on estimators of the disturbances \( u_n \) and not on the true disturbances. As noted above, \( J_n \) equals the vector of derivatives (multiplied by minus one) of the moment conditions (6) w.r.t. \( \rho_n \), and thus \( \Omega_{\hat{\rho}_n}(Y_n) \) has the usual structure, except that here \( \Psi_n \) is not identical to the VC matrix of the moment vector.

Remark 2. From (11), (12), (14) and (15) we see that \( n^{1/2}(\Delta_n - \hat{\rho}_n) \) depends linearly on a vector of linear quadratic forms in the innovations \( \varepsilon_n \) plus a term of order \( o_p(1) \). This result is helpful in establishing the joint distribution of \( \hat{\rho}_n \) with that of estimators of some of the other model parameters of interest. In particular, it may be of interest to derive the joint limiting distribution of \( n^{1/2}\Delta_n \) and \( n^{1/2}(\hat{\rho}_n - \rho_n) \). By Assumption 7, \( n^{1/2}\Delta_n \) is asymptotically linear in \( \varepsilon_n \) and hence the joint limiting distribution can be readily derived using the CLT for linear quadratic forms given in Appendix A. We will illustrate this below within the context of IV estimators for model (1).

We next introduce a consistent estimator for \( \Omega_{\hat{\rho}_n} \). For this purpose let
\[
\tilde{J}_n = \tilde{\Gamma}_n \left[ \begin{array}{c} 1 \\ 2\hat{\rho}_n \end{array} \right] \tag{17}
\]
where \( \tilde{\Gamma}_n \) is defined above by (7) and the discussion after that equation. We next define a HAC type estimator for \( \Psi_n \) whose elements are defined by (13). For this purpose let
\[
\tilde{\Sigma}_n = \text{diag}_{i=1,...,n}(\tilde{\varepsilon}_{i,n}^2)
\]
\(^{10}\)This follows from Corollary F4 in Pötscher and Prucha (1997). Compare also the discussion on pp. 86-87 in that reference.
with \( \tilde{e}_n = (I_n - \tilde{\rho}_n M_n) \tilde{u}_n \). We furthermore need to specify an estimator for \( \tilde{a}_{r,n} = T_n \tilde{\alpha}_{r,n} \). The matrix \( T_n \) introduced in Assumption 7 will in many applications be of the form

\[
T_n = F_n P_n \quad \text{with} \quad F_n = H_n \quad \text{or} \quad F_n = (I_n - \rho_n M_n)^{-1} H_n,
\]

where \( H_n \) is a real nonstochastic \( n \times p \) matrix of instruments, and \( P_n \) is a real nonstochastic \( p \times p \) matrix, with \( p \) as in Assumption 7. In the next section we will consider instrumental variable estimators for the parameters of model (1) and (2). In that section we will see that if \( \Delta_n \) corresponds to these instrumental variable estimators, then the matrix \( T_n \) will indeed have the above structure, and where \( P_n \) can be estimated consistently by some estimator \( \tilde{P}_n \). We now define our estimator for \( T_n \) as

\[
\tilde{T}_n = \tilde{F}_n \tilde{P}_n \quad \text{with} \quad \tilde{F}_n = H_n \quad \text{or} \quad \tilde{F}_n = (I_n - \tilde{\rho}_n M_n')^+ H_n.
\]

In light of (12) it now seems natural to estimate \( \tilde{a}_{r,n} \) by

\[
\tilde{\alpha}_{r,n} = T_n \tilde{\alpha}_{r,n}.
\]

with

\[
\tilde{\alpha}_{r,n} = n^{-1} \left[ D_n (I_n - \tilde{\rho}_n M_n') (A_{r,n} + A_{r,n}') (I_n - \tilde{\rho}_n M_n) \tilde{u}_n \right].
\]

Given the above we now introduce the following HAC type estimator \( \tilde{\Psi}_n = (\tilde{\psi}_{r,s,n}) \) where for \( r, s = 1, 2 \)

\[
\tilde{\psi}_{r,s,n} = (2n)^{-1} tr \left[ (A_{r,n} + A_{r,n}') \tilde{\Sigma}_n (A_{s,n} + A_{s,n}') \tilde{\Sigma}_n \right] + n^{-1} \tilde{a}_{r,n}' \tilde{\Sigma}_n \tilde{a}_{s,n}.
\]

Furthermore, based on \( \tilde{\Psi}_n \) we define the following estimator for \( \tilde{\Omega}_{\tilde{\rho}_n} \):

\[
\tilde{\Omega}_{\tilde{\rho}_n} = (\tilde{J}_n \tilde{\Gamma}_n \tilde{J}_n)^+ \tilde{J}_n' \tilde{\Gamma}_n \tilde{J}_n \tilde{\Psi}_n \tilde{\Gamma}_n \tilde{J}_n (\tilde{J}_n \tilde{\Gamma}_n \tilde{J}_n)^+.
\]

The next theorem establishes the consistency of \( \tilde{\Psi}_n \) and \( \tilde{\Omega}_{\tilde{\rho}_n} \).

**Theorem 3**: (VC matrix estimation) Suppose all of the assumptions of Theorem 2, apart from Assumption 5, hold and that additionally all of the fourth moments of the elements of \( D_n \) are uniformly bounded. Suppose furthermore that (a) that the elements of the nonstochastic matrices \( H_n \) are uniformly bounded in absolute value, (b) \( \sup_n |\rho_n| < 1 \) and the row and column sums of \( M_n \) are bounded uniformly in absolute value by, respectively, one and some finite constant (possibly after a renormalization of the weights matrix and parameter space as discussed in Section 2.2), and (c) \( \tilde{P}_n - P_n = o_p(1) \) with \( P_n = O(1) \). Then

\[
\tilde{\Psi}_n - \Psi_n = o_p(1), \quad \tilde{\Psi}_n^{-1} - \Psi_n^{-1} = o_p(1).
\]

\(^{11}\)The reason for using the generalized inverse is that \( \tilde{\rho}_n \) defined by (9) is not forced to lie in the parameter space, and thus \( I_n - \tilde{\rho}_n M_n \) may be singular (where the probability of this event goes to zero as the sample size increases).
If furthermore Assumption 5 holds, then also
\[ \widetilde{\Omega}_{\hat{\rho}_n} - \Omega_{\hat{\rho}_n} = o_p(1). \]

The hypothesis of zero spatial correlation in the disturbances, i.e., \( H_0 : \rho_n = 0 \), can now be tested in terms of \( N[0, \widetilde{\Omega}_{\hat{\rho}_n}] \).

**Remark 3.** We note that the above theorem also holds if \( \hat{\rho}_n \) is replaced by any other estimator \( \tilde{\rho}_n \) with \( n^{1/2}(\tilde{\rho}_n - \rho_n) = O_p(1) \). In case \( F_n = H_n \) condition (b) can be dropped. The consistency result for \( \tilde{\Psi}_n^{-1} \) verifies that this estimator for \( \Psi_n^{-1} \) can indeed be used in the formulation of an efficient GM estimator, as discussed after Theorem 2.

**Remark 4.** The modules underlying the derivation of Theorems 2 and 3 can be readily extended to cover a wider class of estimators. A crucial underlying ingredient is the CLT for vectors of linear quadratic forms given in Appendix A, which was used to establish the limiting distribution of the vector of linear quadratic forms (11); that CLT is based on Kelejian and Prucha (2001). We emphasize that while in (5) we consider two moment conditions, all of the above results generalize trivially to the case where the GM estimator for \( \rho_n \) corresponds to \( m \) moment conditions
\[ n^{-1}E[\varepsilon_n' A_{1,n} \varepsilon_n, \ldots, \varepsilon_n' A_{m,n} \varepsilon_n]' = 0, \quad (23) \]

where the diagonal elements of \( A_{r,n} \) are zero and the row and column sums of \( A_{r,n} \) are bounded uniformly in absolute value. The focus of this paper is on two-step estimation procedures, which is motivated by their computational simplicity, generality of the first step (where residuals may come from nonlinear models) and, since at least under homoskedasticity, Monte Carlo experiments suggest that very little efficiency is lost, see, e.g., Das, Kelejian and Prucha (2003). Given instruments \( H_n \), one-step GMM estimators for all parameters, i.e., \( \rho_n, \lambda_n, \beta_n \), of the SARAR(1, 1) model could be defined by augmenting those moment conditions (23) by the conditions
\[ n^{-1}E[H_n' \varepsilon_n = n^{-1}E[h_{1,n}' \varepsilon_n, \ldots, h_{p+1,n}' \varepsilon_n]' = 0. \quad (24) \]

with
\[ \varepsilon_n = (I_n - \rho_n M_n)(y_n - X_n \beta_n - \lambda_n W_n y_n). \]

The limiting distribution of the stacked moment vector follows immediately from the CLT for vectors of linear quadratic forms. Theorem 3 establishes consistent estimation of the VC matrix of the vector of (normalized) linear quadratic forms (11). Estimation of the VC matrix of the vector of (normalized) linear quadratic forms corresponding to the stacked moment conditions (23) and (24), is analogous. In fact, in this case estimation simplifies in that the
components of the vector are either quadratic or linear, and the elements of the linear terms \( h_{r,n} \) are observed.\(^\text{12}\)

### 3.4 Joint Asymptotic Distribution of GM Estimator for \( \rho_n \) and Estimators of Other Model Parameters

In the following we discuss how the above results can be extended to obtain the joint asymptotic distribution of the GM estimator for \( \rho_n \) and of other estimators that are asymptotically linear in the innovations \( \varepsilon_n \), i.e., that are of the form considered in Assumption 7. As remarked above, the IV estimators for the regression parameters of model (1) and (2) considered in the next section will be of this form. Based on the joint distribution it will then be possible to test joint hypothesis concerning \( \rho_n \) and other model parameters.

In the following we will give results concerning the joint asymptotic distribution of \( e_{\rho_n} - \rho_n \) and \( \Delta_n \) as considered in Assumptions 4 and 7 in conjunction with the estimation of the disturbances \( u_n \). Clearly, in general it will be of interest to have available results not only concerning the joint asymptotic distribution of \( e_{\rho_n} - \rho_n \) and \( \Delta_n \), but also concerning other estimators, say, \( \Delta_n^* \) that are of the general form considered in Assumption 7. To avoid having to introduce further notation we give our result in terms of \( e_{\rho_n} - \rho_n \) and \( \Delta_n \), but then comment on what changes would be needed in the formulae to accommodate other estimators \( \Delta_n^* \) in place of \( \Delta_n \). The discussion assumes that \( T_n = F_n P_n \) and \( e T_n = e F_n e P_n \) as defined in the previous subsection.

In light of the above discussion we expect that the joint limiting distribution of \( n^{1/2}(e_{\rho_n} - \rho_n) \) and \( n^{1/2} \Delta_n \) will depend on the limiting distribution of \( [n^{-1/2} F_n' \varepsilon_n, \varepsilon_n] \). Observing again that the diagonal elements of the matrices \( A_{r,n} \) are zero it follows from Lemma A.1 that the VC matrix of this vector of linear and linear quadratic form is given by

\[
\Psi_{\circ,n} = \begin{bmatrix}
\Psi_{\Delta,n} & \Psi_{\Delta \rho,n} \\
\Psi'_{\Delta \rho,n} & \Psi_n
\end{bmatrix}
\]  

(25)

with \( \Psi_{\Delta,n} = n^{-1} F_n' \Sigma_n F_n \), \( \Psi_{\Delta \rho,n} = n^{-1} F_n' \Sigma_n [a_{1,n}, a_{2,n}] \) and where \( \Psi_n \) is defined by (13). We shall also employ the following estimator for \( \Psi_{\circ,n} \):

\[
\widetilde{\Psi}_{\circ,n} = \begin{bmatrix}
\widetilde{\Psi}_{\Delta,n} & \widetilde{\Psi}_{\Delta \rho,n} \\
\widetilde{\Psi}'_{\Delta \rho,n} & \widetilde{\Psi}_n
\end{bmatrix}
\]  

(26)

\(^{12}\)Several months after completing this paper we became aware of a paper by Lin and Lee (2005) that considers an SAR(1) model with unknown heteroskedasticity. That paper is complementary to this one, with a focus and extensive discussion of one-step estimation procedures for that model among other things. That paper does not discuss specification issues regarding the parameter space of the autoregressive parameters, which are considered in this paper.
with $\widetilde{\Psi}_{\Delta,n} = n^{-1/2}F_n\tilde{\Sigma}nF_n$, $\widetilde{\Psi}_{\Delta\rho,n} = n^{-1/2}F_n\tilde{\Sigma}n[\tilde{a}_{1,n}, \tilde{a}_{2,n}]$ and where $\widetilde{\Psi}_n$ is defined by (21).

We now have the following result concerning the joint limiting distribution of $n^{1/2}(\tilde{\rho}_n - \rho_n)$ and $n^{1/2}\Delta_n$.

**Theorem 4** Suppose all of the assumptions of Theorem 3 hold, and $\lambda_{\min}(\Psi_o,n) \geq c_{\Psi}>0$. Then

$$\begin{bmatrix}
  n^{1/2}\Delta_n \\
  n^{1/2}(\tilde{\rho}_n - \rho_n)
\end{bmatrix}
= \begin{bmatrix}
  P_n' \\
  0
\end{bmatrix}
\begin{bmatrix}
  0 \\
  (J_n'\bar{\Sigma}_nJ_n)^{-1}J_n'\bar{\gamma}_n
\end{bmatrix}
\begin{bmatrix}
  \Psi_{o,n} + o_p(1),
\end{bmatrix}
(27)
\xi_{o,n} = \Psi_{o,n}^{-1/2} \begin{bmatrix}
  n^{-1/2}F_n \varepsilon_n, \nu_n
\end{bmatrix}' \overset{d}{\rightarrow} N(0, I_{p+2}).

Furthermore let

$$\begin{align*}
\Omega_{o,n} &= \begin{bmatrix}
  P_n' \\
  0
\end{bmatrix}
\begin{bmatrix}
  0 \\
  (J_n'\bar{\Sigma}_nJ_n)^{-1}J_n'\bar{\gamma}_n
\end{bmatrix}
\begin{bmatrix}
  P_n \\
  0
\end{bmatrix}
\begin{bmatrix}
  0 \\
  \bar{\Sigma}_nJ_n(J_n'\bar{\Sigma}_nJ_n)^{-1}
\end{bmatrix}
(28)
\end{align*}
$$

$$\begin{align*}
\tilde{\Omega}_{o,n} &= \begin{bmatrix}
  \tilde{P}_n' \\
  0
\end{bmatrix}
\begin{bmatrix}
  0 \\
  (J_n'\tilde{\Sigma}_nJ_n)^{-1}J_n'\tilde{\gamma}_n
\end{bmatrix}
\begin{bmatrix}
  \tilde{P}_n \\
  0
\end{bmatrix}
\begin{bmatrix}
  0 \\
  \tilde{\Sigma}_nJ_n(J_n'\tilde{\Sigma}_nJ_n)^{-1}
\end{bmatrix}
(29)
\end{align*}
$$

then $\tilde{\Psi}_{o,n} - \Psi_{o,n} = o_p(1)$, $\tilde{\Omega}_{o,n} - \Omega_{o,n} = o_p(1)$, and $\Psi_{o,n} = O(1)$, $\Omega_{o,n} = O(1)$.

The above theorem implies that the difference between the joint cumulative distribution function of $n^{1/2}[\Delta_n', (\tilde{\rho}_n - \rho_n)]'$ and that of $N[0, \Omega_{o,n}]$ converges pointwise to zero, which justifies the use of the latter distribution as an approximation of the former. The theorem also states that $\Omega_{o,n}$ is a consistent estimator for $\Omega_{o,n}$.

**Remark 5.** The above result generalizes readily to cases where we are interested in the joint distribution between $\tilde{\rho}_n - \rho_n$ and some other estimator, say, $\Delta^*_n$, where $n^{1/2}\Delta^*_n = n^{-1/2}T_n'\varepsilon_n + o_p(1)$, $T^*_n = F'_nP^*_n$ and $\bar{T}_n = \bar{F}'_n\bar{P}^*_n$, assuming that analogous assumptions are maintained for this estimator. In particular, the results remain valid, but with $\Psi_{\Delta,n} = n^{-1}F'_n\Sigma_nF_n$, $\Psi_{\Delta\rho,n} = n^{-1}F'_n\Sigma_n[\tilde{a}_{1,n}, \tilde{a}_{2,n}]$, $\tilde{\Psi}_{\Delta,n} = n^{-1}\tilde{F}'_n\Sigma_n\tilde{F}_n$, $\tilde{\Psi}_{\Delta\rho,n} = n^{-1}\tilde{F}'_n\Sigma_n[\tilde{a}_{1,n}, \tilde{a}_{2,n}]$, and $P_n, \tilde{P}_n$ replaced by $P^*_n, \tilde{P}^*_n$.

### 4 Instrumental Variable Estimator for $\delta_n$

As remarked, the consistency and asymptotic normality results developed in an important paper by Lee (2004) for the quasi-ML estimator for the SARAR(1,1) model defined by (1) and (2) under the assumption of homoskedastic innovations do not carry over to the case where the innovations are heteroskedastic. In fact, under heteroskedasticity the limiting objective function of the quasi-ML
estimator would generally not be maximized at the true parameter values, and therefore the quasi-ML estimator would be inconsistent. Also, the asymptotic normality results developed by Kelejian and Prucha (1998), Kelejian, Prucha and Yuzefovich (2004) and Lee (2003) for instrumental variable (IV) estimators of the SARAR(1,1) model do not carry over to the case where the innovations are heteroskedastic. In the following we provide results concerning the asymptotic distribution of IV estimators allowing the innovations to be heteroskedastic. More specifically, we will show that the considered IV estimators satisfy certain conditions such that their asymptotic distribution can be readily obtained via Theorem 4. We also allow for a more general definition of the parameter space of the spatial autoregressive parameters to avoid certain pitfalls discussed in Section 2.

4.1 Instruments

It is evident from (3) that in general \( W_n y_n \) will be correlated with the disturbances \( u_n \), which motivates the use of IV estimation procedures. We maintain the following assumptions w.r.t. the \( n \times k \) regressor matrices \( X_n \), and the \( n \times p_* \) instrument matrices \( H_n \).

**Assumption 8**: The regressor matrices \( X_n \) have full column rank (for \( n \) large enough). Furthermore, the elements of the matrices \( X_n \) are uniformly bounded in absolute value.

**Assumption 9**: The instrument matrices \( H_n \) have full column rank \( p_* \geq k+1 \) (for all \( n \) large enough). Furthermore, the elements of the matrices \( H_n \) are uniformly bounded in absolute value. Additionally \( H_n \) is assumed to, at least, contain the linearly independent columns of \( (X_n, M_n X_n) \).

**Assumption 10**: The instruments \( H_n \) satisfy furthermore:

(a) \( Q_{HH} = \lim_{n \to \infty} n^{-1} H_n' H_n \) is finite, and nonsingular.

(b) \( Q_{HZ} = p \lim_{n \to \infty} n^{-1} H_n' Z_n \) and \( Q_{HMZ} = p \lim_{n \to \infty} n^{-1} H_n' M_n Z_n \) are finite and have full column rank. Furthermore, let \( Q_{HZ}(\rho_n) = Q_{HZ} - \rho_n Q_{HMZ} \), then the smallest eigenvalue of \( Q_{HZ}(\rho_n) Q_{HH} Q_{HZ}(\rho_n) \) is bounded away from zero uniformly in \( n \).

(c) \( Q_{HSH} = \lim_{n \to \infty} n^{-1} H_n' \Sigma_n H_n \) is finite and nonsingular.

The above assumptions are similar to those maintained in Kelejian and Prucha (1998, 2004), and Lee (2003), and so a discussion which is quite similar to those given in those papers also applies here. Regarding the specification of the instruments \( H_n \) observe first that

\[
E(W_n y_n) = W_n (I_n - \lambda_n W_n)^{-1} X_n \beta_n = \sum_{i=0}^{\infty} \lambda_n^i W_n^{i+1} X_n \beta_n \tag{30}
\]
provided that the characteristic roots of $\lambda_n W_n$ are less than one in absolute value; compare Lemma 1 and 2 concerning the choice of the parameter space for $\lambda_n$. The instrument matrices $H_n$ will be used to instrument $Z_n = (X_n, W_n Y_n)$ and $M_n Z_n = (M_n X_n, M_n W_n Y_n)$ in terms of their predicted values from a least squares regression on $H_n$, i.e., $\bar{Z}_n = P_{H_n} Z_n$ and $\bar{M}_n Z_n = P_{H_n} M_n Z_n$ with $P_{H_n} = H_n (H_n' H_n)^{-1} H_n'$. Towards approximating the ideal instruments $E(Z_n) = (X_n, W_n E(Y_n))$ and $E(M_n Z_n) = (M_n X_n, M_n W_n E(Y_n))$ it seems reasonable, in light of (30), to take $H_n$ to be a subset of the linearly independent columns of

$$(X_n, W_n X_n, W_n^2 X_n, \ldots, W_n^q X_n, M_n X_n, M_n W_n X_n, \ldots, M_n W_n^q X_n) \quad (31)$$

where $q$ is a pre-selected finite constant.$^{13}$ We note that if $H_n$ is selected as in (31) it follows from Assumptions 3 and 8 that its elements will be bounded in absolute value as postulated in Assumption 9. Assumption 9 ensures that $X_n$ and $M_n X_n$ are instrumented by themselves. Finally we note that the assumption that $H_n$ has full column rank could be relaxed at the expense of working with generalized inverses.

### 4.2 Definition, Consistency and Asymptotic Normality

Towards estimating the model (1) and (2) we propose a three step procedure. In the first step the model is estimated by two stage least squares (2SLS) using the instruments $H_n$. In the second step the autoregressive parameter, $\rho_n$, is estimated using the generalized moments estimation approach from Section 3 based on the 2SLS residuals obtained via the first step. In the third step, the regression model in (1) is re-estimated by 2SLS after transforming the model via a Cochrane-Orcutt-type transformation to account for the spatial correlation.

More specifically, the first step 2SLS estimator is defined as:

$$\delta_n = (\bar{Z}_n' Z_n)^{-1} \bar{Z}_n' y_n, \quad (32)$$

where $\bar{Z}_n = P_{H_n} Z_n = (X_n, W_n Y_n)$ and $\bar{W}_n y_n = P_{H_n} W_n Y_n$. In the second step we estimate $\rho_n$ by the GM procedure defined by (9) based on the 2SLS residuals $\bar{u}_n = y_n - Z_n \delta_n$. We denote the GM estimator again as $\rho_n$.

The next lemma shows that various assumptions maintained in Section 3 w.r.t. the estimator of the regression parameters and estimated residuals are automatically satisfied by the 2SLS estimator $\delta_n$ and the corresponding residuals.

**Lemma 3**: Suppose Assumptions 1-3 and 8-10 hold, and $\sup_n \| \beta_n \| < \infty$. Let $D_n = -Z_n$, then the fourth moments of the elements of $D_n$ are uniformly

$^{13}$In Kelejian, Prucha, and Yuzefovich (2004), who considered the case of homoskedastic innovations, the instruments were determined more generally by taking $q$ as a function of the sample size $n$, i.e., $q_n$, such that $q_n \to \infty$ as $n \to \infty$. Their Monte Carlo results suggest that $q = 2$ may be sufficient for many applications.
bounded, Assumption 6 holds, and:

(a) $n^{1/2}(\delta_n - \delta_n) = n^{-1/2}T_n'\varepsilon_n + o_p(1)$ with $T_n = F_nP_n$ and where

$$P_n = Q_{HH}^{-1}Q_{HZ}^{-1}[Q_{HZ}Q_{HH}^{-1}Q_{HZ}]^{-1},$$
$$F_n = (I_n - \rho_nM_n')^{-1}H_n.$$

(b) $n^{-1/2}T_n'\varepsilon_n = O_p(1),$

(c) $P_n = O_p(1)$ and $\bar{P}_n - P_n = o_p(1)$ for

$$\bar{P}_n = (n^{-1}H_n'H_n)^{-1}(n^{-1}H_n'Z_n) \times [(n^{-1}Z_nH_n)(n^{-1}H_n'H_n)^{-1}(n^{-1}H_n'Z_n)]^{-1},$$

The condition $\sup_n \|\beta_n\| < \infty$ is trivially satisfied if $\beta_n = \beta$. Of course, parts (a) and (b) together imply that $\delta_n$ is $n^{1/2}$-consistent for $\delta_n$.

Clearly $\bar{u}_n = u_n + D_n\Delta_n$ with $D_n = -Z_n$ and $\Delta_n = \bar{\delta}_n - \delta_n$. Lemma 3 shows that in essence under Assumptions 1-3 and 8-10 the 2SLS residuals automatically satisfy the conditions postulated in Assumptions 4, 6 and 7 with $D_n = -Z_n$, $\Delta_n = \bar{\delta}_n - \delta_n$ and $T_n$ as specified in the lemma. Consequently the results concerning consistency and asymptotic normality of the GM estimator for $\rho_n$ in Theorems 1 and 2 apply in particular to the GM estimator $\bar{\rho}_n$ based on 2SLS residuals. Lemma 3 also establishes that the fourth moments of the elements of $D_n = -Z_n$ are uniformly bounded. The lemma also gives explicit expression for $P_n$ and $\bar{P}_n$ and verifies the conditions postulated w.r.t. to those matrices in Theorems 3 and 4. Hence the results of those two theorems also cover the GM estimator $\bar{\rho}_n$ and the 2SLS estimator $\delta_n$. In particular, Theorem 4 gives the joint limiting distribution of $n^{1/2}(\bar{\rho}_n - \rho_n)$ and $n^{1/2}\Delta_n = n^{1/2}(\bar{\delta}_n - \delta_n)$ where $D_n = -Z_n$, the matrices $P_n$, $F_n$, $P_n$ are as in Lemma 3, and $F_n = (I_n - \bar{\rho}_nM_n')^+H_n$.14

We now turn to the third step. Applying a Cochrane-Orcutt-type transformation to (1) yields

$$y_{n*}(\rho_n) = Z_{n*}(\rho_n)\delta_n + \varepsilon_n,$$

where $y_{n*}(\rho_n) = y_n - \rho_nM_ny_n$ and $Z_{n*}(\rho_n) = Z_n - \rho_nM_nZ_n$. Our estimator $\hat{\delta}_n$ for $\delta_n$ in this third step is now defined as the 2SLS procedure applied to the transformed model (33) after replacing $\rho_n$ by $\bar{\rho}_n$. That is,

$$\hat{\delta}_n = \hat{Z}_{n*}(\bar{\rho}_n)'Z_{n*}(\bar{\rho}_n)^{-1}\hat{Z}_{n*}(\bar{\rho}_n)'y_{n*}(\bar{\rho}_n)$$

where $\hat{Z}_{n*}(\bar{\rho}_n) = PH_nZ_{n*}(\bar{\rho}_n)$. To express the dependence of $\hat{\delta}_n$ on $\bar{\rho}_n$ we also write $\hat{\delta}_n = \delta_n(\bar{\rho}_n)$.14

14 An alternative estimation approach is to use a HAC procedure to estimate the variance covariance matrix of the 2SLS estimator. Such an approach was considered in Pitsak, Slade, and Brett (2002) and Kelejian and Prucha (2005). While such an approach is more robust, it does not yield a simple testing strategy for a joint test of spatial dependencies in the endogenous, exogenous and disturbances.
The next lemma shows again that various assumptions maintained in Section 3 w.r.t. the estimator of the regression parameters and estimated residuals are automatically satisfied by the generalized spatial 2SLS estimator $\hat{\delta}_n$ and corresponding residuals.

**Lemma 4**: Suppose the assumptions of Lemma 3, and let $\hat{\delta}_n(\rho_n)$ be as defined by (34), where $\tilde{\rho}_n$ is any $n^{1/2}$-consistent estimator for $\rho_n$ (such as the GM estimator $\tilde{\rho}_n$ based on 2SLS residuals). Then

(a) $n^{1/2}[\hat{\delta}_n(\rho_n) - \delta_n] = n^{-1/2}T_n^*\varepsilon_n + o_p(1)$ with $T_n^* = F_n^*P_n^*$ and where

$$P_n^* = Q_{HH}^{-1}Q_{HZ}\sigma(\rho_n)[Q_{HZ}\sigma(\rho_n)Q_{HH}^{-1}Q_{HZ}\sigma(\rho_n)]^{-1}$$

$$F_n^* = H_n.$$

(b) $n^{-1/2}T_n^*\varepsilon_n = O_p(1)$.

(c) $P_n^* = O_p(1)$ and $P_n^* - P_n = o_p(1)$ for

$$P_n^* = (n^{-1}H_n^*H_n)^{-1}(n^{-1}H_n^*Z_{n*}(\tilde{\rho}_n)) \times$$

$$[n^{-1}Z_{n*}(\tilde{\rho}_n)H_n(n^{-1}H_n^*H_n)^{-1}(n^{-1}H_n^*Z_{n*}(\tilde{\rho}_n))]^{-1}.$$

Frequently we will be interested in the joint distribution of the generalized spatial 2SLS estimator $\hat{\delta}_n(\rho_n)$ and the GM estimator $\tilde{\rho}_n$. In light of Lemma 3 and 4 the limiting distribution of $n^{1/2} \left[ (\hat{\delta}_n - \delta_n)'(\tilde{\rho}_n - \rho_n) \right]$ now follows immediately from Theorem 4 and Remark 5 after that theorem, with $\Delta_n^* = \delta_n - \delta_n$. The asymptotic variance covariance matrix of its corresponding estimator are given by (28) and (29) with modifications as described in Remark 5 and $D_n = -Z_{n*}\hat{\delta}_n$. The expressions for the matrices $P_n, F_n, P_n$ are as in Lemma 3, and $F_n = (I_n - \tilde{\rho}_nM_n)^{-1}H_n$. The expressions for the matrices $P_n^*, F_n^*, P_n^*$ are as in Lemma 4, and $F_n^* = H_n$. The joint distribution can then be used to test in particular the joint hypothesis $H_0: \lambda_n = \rho_n = 0$ in the usual manner.

Finally, consider the estimated residuals corresponding to $\hat{\delta}_n$, i.e., $u_n^* = y_n - Z_n\hat{\delta}_n = u_n + D_n\Delta_n^*$. Clearly, in light of Lemma 4 we could use those residuals to define a corresponding GM estimator based on those residuals, and a discussion analogous to that after Lemma 3 would also apply here. Of course, further iterative procedures are possible, and their asymptotic properties would again be covered by the asymptotic theory developed above.

**Remark 6.** The estimation theory of Section 3 was developed under a set of fairly general assumptions. The results given in this section are illustrative as to how Assumptions 4, 6, 7 can be implied for the 2SLS and GS2SLS estimator of the SARAR(1,1) model from the more primitive Assumptions 8 - 10. The assumption that $X_n$ is nonstochastic rules out the presence of endogenous regressors (apart from the spatial lag $W_n y_n$). Now suppose that $X_n = [X_n, Y_n]$ and correspondingly $D_n = -Z_n = -[X_n, Y_n, W_n y_n]$, where $X_n$ satisfies Assumptions 8-10, with $X_n$ replaced by $X_n$ (including in the formulation of the
instruments), and where $Y_n$ is a matrix of endogenous variables. Then given
the fourth moments of the elements of $D_n$ are uniformly bounded, and Assumption 6 holds, parts (a),(b) and (c) of Lemmata 3 and 4 still hold but with
\[ Z_n = P_{H_n} X_n, P_{H_n} Y_n, P_{H_n} W_n Y_n \]
and
\[ \tilde{Z}_{n*}(\tilde{\rho}_n) = P_{H_n} Z_{n*}(\tilde{\rho}_n) \]
\[ = \left[ (I_n - \tilde{\rho}_n M_n) X_n, P_{H_n} (I_n - \tilde{\rho}_n M_n) Y_n, P_{H_n} (I_n - \tilde{\rho}_n M_n) W_n Y_n \right] . \]
In specifying a full system of equations analogous to Kelejian and Prucha (2004)
one could furthermore develop more primitive conditions that ensure the mo-
mement condition for the elements of $D_n$ as well as Assumption 6.

5 Some Monte Carlo Results

In order to obtain some insights relating to the small sample properties of our
suggested estimators, as well as the quasi-maximum likelihood estimator, we
undertook a limited Monte Carlo study. Our study is limited in that we only
considered one set of parameter values. On the other hand, we consider four
different sample sizes, as well as a case in which the innovations are heteroskedas-
tic, and one in which they are homoskedastic. Although our results are quite
suggestive, clearly a more extensive Monte Carlo study is of interest.\textsuperscript{15}

Our Monte Carlo study relates to the model in (1) and (2) with $M = W$.\textsuperscript{16}
We also took $X = [x_1, x_2]$ to be an $n \times 2$ matrix of observations on two ex-
egogenous variables. The four values of the sample size, $n$, we considered are
250, 500, 1000, and 2000. In all the simulations, the values of $x_1$ and $x_2$ are
based on data described in Kelejian and Robinson (1992) which relate to income
per capita and the percent of rental housing in 1980 in 760 counties in the US
mid-western states. The 760 observations on the income and rental variables
were normalized to have zero mean and unit variance. We repeated the sample
of 760 observations to generate samples of larger sizes. For sample sizes $n = 250$
and 500 we used the first 250 or 500 observations. In formulating the $W$
matrix we took guidance from the specification considered in Kelejian and Prucha
(1999). They considered a weights matrix, to which they referred to as “5 ahead
and 5 behind”. The reason for their designation is that the non-zero elements
in the $i$-th row of $W$ are in positions $i + 1, \ldots, i + 5, i + 3, \text{ and } i - 1, \ldots, i - 5$,
for $i = 6, \ldots, n - 5$. Thus, in these rows the $i$-th element of $u$ is directly related
to the five elements of $u$ directly after it and to the five directly before. The
matrix $W$ is defined in a circular world so that, e.g., in the first row the non-
zero elements are in positions 2, \ldots, 6 (i.e., five ahead) and $n, \ldots, n - 5$, (i.e., five

\textsuperscript{15}We note that such a study is currently being conducted by Irani Arraiz, David Drukker
and the authors, but given its dimensions such a study is outside of the scope of the present
paper.
\textsuperscript{16}For ease of notation, in this section we do not indicate the possible dependence of various
quantities on the sample size.
2SLS residuals, and denote the estimator as residual. We denote the estimator as ized spatial 2SLS estimator Monte Carlo experiment we performed 2000 Monte Carlo iterations. dependent vector \( y \) \( \sigma \) deviations of \( \delta \) for the asymptotic variance covariance matrix of the quasi ML estimator. the inverse of the negative Hessian of the log-likelihood function as the estimator are computed based on normalized in that in each row the nonzero elements were set equal to \( 1/d_i \). rejection rates range from are reasonably close to the nominal value of \( 0.05 \). For example, for \( n = 1000 \), the rejection rates range from 0.046 to 0.054. This suggests that the derived large
sample distribution and the developed estimators of the asymptotic variance covariance matrix are indeed useful towards approximating the small sample distribution. The rejection rates for the ML estimators range, as is expected due to the serious biases, from 0.176 to 1.000.

Under homoskedasticity the expected log-likelihood function is maximized at the true parameter values, and both the generalized spatial 2SLS/GM estimators and ML estimators show very little bias. We also note that the loss of efficiency of the generalized spatial 2SLS/GM estimators relative to the ML estimators seems generally modest.

6 Summary and Suggestions for Further Research

In this paper we introduce a new class of GM estimators for the autoregressive parameter of a spatially autoregressive disturbance process allowing for innovations with unknown heteroskedasticity. The estimation theory for the GM estimators is developed in a modular fashion under a fairly general set of assumptions, and should cover many (linear and nonlinear) models. The general theory is then utilized to establish the consistency and asymptotic normality of IV estimators for the regression parameters for an important class of spatial models, frequently referred to as SARAR(1, 1) models. The paper provides results concerning the joint asymptotic distribution of the GM estimator for the autoregressive parameter of the disturbance process and IV estimators for the model regression parameters. Among other things, the results allow for a joint test that the autoregressive parameters corresponding to the spatial lags of the dependent variable and disturbance term are both zero. We also provide a discussion of the specification of the parameter space for SARAR(1, 1) models. We demonstrate that a computationally simple re-scaling of the weights matrix leads to an equivalent model containing a (re-scaled) autoregressive parameter which has a user-friendly parameter space. Unfortunately, previous studies in the literature have often re-scaled their weights matrix in such a way that the “before and after” scaled models are not equivalent.

One suggestion for further research is to extend the results to panel data. A further suggestion for future research would be a comprehensive Monte Carlo study which focuses on the small sample properties of the considered estimators. Such a study may also consider comparisons with the quasi-ML estimator (specified under homoskedasticity).
Appendix: CLT for Vectors of Linear Quadratic Forms

In the following we state, for the convenience of the reader, a central limit theorem (CLT) for vectors of linear quadratic forms with heteroskedastic innovations. This CLT is based on a CLT given in Kelejian and Prucha (2001) for the scalar case. We first state a lemma that collects useful results on the mean and VC matrix between (and as a special case the variance of) linear quadratic forms.

Lemma A.1: Let \( \zeta = (\zeta_1, \ldots, \zeta_n)' \) be a random vector with zero mean and positive definite variance covariance matrix \( \Xi \), let \( A = (a_{ij}) \) and \( B = (b_{ij}) \) be \( n \times n \) nonstochastic symmetric matrices, and let \( a \) and \( b \) be \( n \times 1 \) nonstochastic vectors. Consider the decomposition \( \Xi = SS' \), let \( A^* = (a_{ij},*) = S_0A S_0 \) and \( B^* = (b_{ij},*) = S_0B S_0 \), and let \( a^* = S_0a \) and let \( b^* = S_0b \). Furthermore let \( \eta = (\eta_1, \ldots, \eta_n)' = S^{-1} \zeta \). Then assuming that the elements of \( \eta \) are independently distributed with zero mean, unit variance, and finite third and fourth moments \( E(\eta_i^3) = \mu^{(3)}_{\eta_i} \) and \( E(\eta_i^4) = \mu^{(4)}_{\eta_i} \) we have

\[
E(\zeta'A\zeta + a_0\zeta) = \text{tr}(A\Xi),
\]

\[
cov(\zeta'A\zeta + a'\zeta, \zeta'B\zeta + b'\zeta) = 2\text{tr}(A\Xi B\Xi) + a'\Xi b + \sum_{i=1}^n a_{ii,*}b_{ii,*} + \sum_{i=1}^n (a_{i,*}b_{i,*} + b_{i,*}a_{i,*})\mu^{(3)}_{\eta_i}.
\]

Remark A.1. The above expression for the covariance exploits the independence of the elements of \( \eta \). A convenient way to obtain these expressions is to re-write the linear quadratic form as a sum of martingale differences as, e.g., in Kelejian and Prucha (2001, Appendix A). If the diagonal elements of \( A^* \) and \( B^* \) are zero the last two terms drop out from the expression for the covariance, and so one need only assume the existence of second moments. The last two terms also drop out from the expression for the covariance in the case where \( \zeta \) – or equivalently \( \eta \) – is normally distributed, since in this case \( \mu^{(3)}_{\eta_i} = 0 \) and \( \mu^{(4)}_{\eta_i} = 3 \). Of course, the variance of a linear quadratic form is obtained as the special case where \( A = B \) and \( a = b \). Obviously, in case \( A \) and \( B \) are not symmetric the above formulae apply with \( A \) and \( B \) replaced by \((A + A')/2\) and \((B + B')/2\).

Consider the linear quadratic forms \( (r = 1, \ldots, m) \)

\[
Q_{r,n} = \xi_n'A_{r,n}\xi_n + a'_{r,n}\xi_n
\]

where \( \xi_n = (\xi_{1,n}, \ldots, \xi_{n,n})' \) is an \( n \times 1 \) random vector, \( A_{r,n} = (a_{ij,r,n})_{i,j=1,\ldots,n} \) is an \( n \times n \) nonstochastic real matrix, and \( a_{r,n} = (a_{1,r,n}, \ldots, a_{n,r,n})' \) is an \( n \times 1 \) nonstochastic real vector. We maintain the following assumptions:
Assumption A.1 The real valued random variables of the array \( \{ \xi_{i,n} : 1 \leq i \leq n, n \geq 1 \} \) satisfy \( E\xi_{i,n} = 0 \). Furthermore, for each \( n \geq 1 \) the random variables \( \xi_{1,n}, \ldots, \xi_{n,n} \) are totally independent.

Assumption A.2 For \( r = 1, \ldots, m \) the elements of the array of real numbers \( \{ a_{i,j,r,n} : 1 \leq i, j \leq n, n \geq 1 \} \) satisfy \( a_{i,j,r,n} = a_{j,i,r,n} \) and \( \sup_{1 \leq j \leq n, n \geq 1} |a_{i,j,r,n}| < \infty \). The elements of the array of real numbers \( \{ a_{i,r,n} : 1 \leq i \leq n, n \geq 1 \} \) satisfy \( \sup_{n \geq 1} n^{-1} \sum_{i=1}^{n} |a_{i,r,n}|^{2+\eta_1} < \infty \) for some \( \eta_1 > 0 \).

Assumption A.3 For \( r = 1, \ldots, m \) one of the following two conditions holds:

(a) \( \sup_{1 \leq i \leq n, n \geq 1} E|\xi_{i,n}|^{2+\eta_2} < \infty \) for some \( \eta_2 > 0 \) and \( a_{ii,r,n} = 0 \).

(b) \( \sup_{1 \leq i \leq n, n \geq 1} E|\xi_{i,n}|^{4+\eta_2} < \infty \) for some \( \eta_2 > 0 \) (but possibly \( a_{ii,r,n} \neq 0 \)).

Let \( \mu_{Q_{r,n}} \) and \( \sigma_{Q_{rs,n}} \) denote the mean of \( Q_{r,n} \) and the covariance between \( Q_{r,n} \) and \( Q_{s,n} \), respectively, for \( r, s = 1, \ldots, m \). Then it follows immediately from Lemma A.1 that under Assumptions A.1 and A.3 \( \mu_{Q_{r,n}} = \sum_{i=1}^{n} a_{ii,r,n} \sigma_{i,n}^2 \), \( \sigma_{Q_{rs,n}} = 2 \sum_{i=1}^{n} \sum_{j=1}^{n} a_{i,j,r,n} a_{i,j,s,n} \sigma_{i,n}^2 \sigma_{j,n}^2 + \sum_{i=1}^{n} a_{i,r,n} a_{i,s,n} \sigma_{i,n}^2 + \sum_{i=1}^{n} a_{ii,r,n} a_{ii,s,n} \mu_{i,n}^{(3)} \).

where \( \sigma_{i,n}^2 = E\xi_{i,n}^2 \), \( \mu_{i,n}^{(3)} = E\xi_{i,n}^3 \) and \( \mu_{i,n}^{(4)} = E\xi_{i,n}^4 \). In case Assumption A.3(a) holds, the mean of \( Q_{r,n} \) is zero and the last two terms drop out from the expression for the variance.

In the following we give a CLT for the \( m \times 1 \) vector of linear quadratic forms \( \mathbf{V}_n = [ Q_{1,n}, \ldots, Q_{m,n} ]' \).

Let \( \mu_{\mathbf{V}_n} = E\mathbf{V}_n = [ \mu_{Q_{1,n}}, \ldots, \mu_{Q_{m,n}} ]' \) and \( \Sigma_{\mathbf{V}_n} = [ \sigma_{Q_{rs,n}} ]_{r,s=1,\ldots,m} \) denote the mean and VC matrix of \( \mathbf{V}_n \), respectively. We then have the following theorem.

Theorem A.1 Suppose Assumptions A.1-A.3 hold and \( n^{-1} \lambda_{\min}(\Sigma_{\mathbf{V}_n}) \geq c \) for some \( c > 0 \). Let \( \Sigma_{\mathbf{V}_n}^{-1/2} (\Sigma_{\mathbf{V}_n}^{1/2} (\mathbf{V}_n - \mu_{\mathbf{V}_n}) ) \xrightarrow{d} N(0, I_m) \).
To show that (A.1) holds we verify that Prucha (2001) holds for the elements of λ where n of Theorem 1 in Kelejian and Prucha (2001). Assumptions A.1 and A.3 are quadratic forms Prucha (2001) w.r.t. the variance of a linear quadratic form for each of the linear automatically implies the assumption maintained in Theorem 1 of Kelejian and n greater than or equal to the smallest eigenvalue of that matrix it follows that Remark A.2. Since the diagonal elements of a positive definite matrix are assumed to hold for n > n0 where n0 is finite.

Proof of Theorem A.1: Let α be some arbitrary m × 1 vector with ∥α∥ = 1, let
\[ \pi_n = (\pi_{1,n}, \ldots, \pi_{m,n}) = n^{1/2} \alpha^\prime \Sigma_n^{-1/2}, \]
and define
\[ Q_n = n^{1/2} \alpha^\prime \Sigma_n^{-1/2} V_n = \sum_{r=1}^m \pi_{r,n} \xi_r A_{r,n} \xi_n + \sum_{r=1}^m \pi_{r,n} a_{r,n}^\prime \xi_n = \xi_n^\prime \mathbf{C}_n \xi_n + \mathbf{d}_n^\prime \xi_n, \]
where \( \mathbf{C}_n = \sum_{r=1}^m \pi_{r,n} A_{r,n} \) and \( \mathbf{d}_n = \sum_{r=1}^m \pi_{r,n} a_{r,n} \). Observe that
\[ \mu_{Q_n} = E Q_n = n^{1/2} \alpha^\prime \Sigma_n^{-1/2} \mu_{V_n} = \sum_{r=1}^m \pi_{r,n} \mu_{Q_{r,n}}, \]
\[ \sigma_{Q_n}^2 = var(Q_n) = na\alpha^\prime \Sigma_n^{-1/2} \Sigma_n \Sigma_n^{-1/2} \alpha = n. \]

To prove the theorem, using the Cramér–Wold device, it suffices to show that
\[ a^\prime \Sigma_n^{-1/2} (V_n - \mu_{V,n}) = \frac{Q_n - \mu_{Q,n}}{\sigma_{Q,n}} \overset{d}{\rightarrow} \mathcal{N}(0,1). \] (A.1)

To show that (A.1) holds we verify that \( \xi_n \) and \( \mathbf{C}_n \) and \( \mathbf{d}_n \) satisfy the conditions of Theorem 1 in Kelejian and Prucha (2001). Assumptions A.1 and A.3 are identical to Assumptions 1 and 3 in Kelejian and Prucha (2001). Furthermore, \( n^{-1} \sigma_{Q_n}^2 = 1 \). Thus it suffices to verify that Assumption 2 in Kelejian and Prucha (2001) holds for the elements of \( \mathbf{C}_n \) and \( \mathbf{d}_n \).

Clearly \( \lambda_{\max}(n \Sigma_n^{-1}) = 1/\lambda_{\min}(n^{-1} \Sigma_n) \leq 1/c \). By Proposition 43 in Dhrymes (1978, p. 470) the matrices \( n \Sigma_n^{-1} = n \Sigma_n^{-1/2} \Sigma_n^{-1/2} \) and \( n \Sigma_n^{-1/2} \Sigma_n^{-1/2} \) have the same characteristic roots. Thus \( \|\pi_n\|^2 = \alpha^\prime (n \Sigma_n^{-1/2} \Sigma_n^{-1/2}) \alpha \leq \lambda_{\max}(n \Sigma_n^{-1/2} \Sigma_n^{-1/2}) \|\alpha\|^2 = \lambda_{\max}(n \Sigma_n^{-1}) \leq 1/c < \infty \), and hence \( |\pi_{r,n}| \leq c_x \) where the constant \( c_x = 1/\sqrt{c} \).

Observe that
\[ |c_{ij,n}| = \sum_{r=1}^m |\pi_{r,n}| |a_{ij,r,n}| \leq c_x \sum_{r=1}^m |a_{ij,r,n}| \]
and hence
\[ \sup_{1 \leq i \leq m, n \geq 1} \sum_{i=1}^n |c_{ij,n}| \leq c_x \sum_{r=1}^m \sup_{1 \leq j \leq m, n \geq 1} \sum_{i=1}^n |a_{ij,r,n}| < \infty. \]
in light of Assumption A.2. This shows that the elements of $C_n$ satisfy Assumption 2 in Kelejian and Prucha (2001).

Next observe that
\[ \left| d_{i,n} \right|^{2+\eta_1} \leq \left( \sum_{r=1}^{m} |\pi_{r,n}| |a_{i,r,n}| \right)^{2+\eta_1} \leq c_{2+\eta_1}^{2+\eta_1} \left( \sum_{r=1}^{m} |a_{i,r,n}| \right)^{2+\eta_1} \]

and hence
\[ \sup_n n^{-1} \sum_{i=1}^{n} \left| d_{i,n} \right|^{2+\eta_1} \leq c_{2+\eta_1}^{2+\eta_1} m^{2+\eta_1} \sum_{r=1}^{m} \left( \sup_n n^{-1} \sum_{i=1}^{n} |a_{i,r,n}| \right)^{2+\eta_1} \]

**B Appendix: Proofs for Section 2**

**Proof of Lemma 1**: Clearly $I_n - \lambda W_n$ is non-singular for $\lambda = 0$. For $\lambda \neq 0$ we have $\det(I_n - \lambda W_n) = (-\lambda)^n \det(W_n - \lambda^{-1} I_n)$. Consequently $I_n - \lambda W_n$ is non-singular for values of $\lambda^{-1} \notin \{\nu_1,n, \ldots, \nu_{n,n}\}$. In particular, $I_n - \lambda W_n$ is non-singular for $|\lambda^{-1}| > \tau_n$. Rewriting this last inequality as $|\lambda| < \tau_n^{-1}$ completes the proof.

**Proof of Lemma 2**: As an immediate consequence of Geršgorin’s Theorem — see, e.g., Horn and Johnson (1985), pp. 344-346 — we have $\tau_n = \max\{|\nu_{1,n}|, \ldots, |\nu_{n,n}|\} \leq \tau_n^*$. The claim now follows from Lemma 1.

**C Appendix: Proofs for Section 3**

**Remark C.1.** Suppose the row and column sums of the $np \times np$ matrices $A_n = (a_{ij,n})$ are bounded uniformly in absolute value by some finite constants $c_A$, then $\sum_{i=1}^{np} |a_{ij,n}|^q \leq c_A^q$ for $q > 1$. This result is trivially seen to hold since $\sum_{i=1}^{np} |a_{ij,n}|^q = c_A^{-1} \sum_{i=1}^{np} |a_{ij,n}| a_{ij,n}/c_A |a_{ij,n}/c_A|^{q-1} \leq c_A^{-1} \sum_{i=1}^{np} |a_{ij,n}| \leq c_A^q$.

We shall make use of the following lemma.

**Lemma C.1**: Suppose the row and column sums of the real nonstochastic $n \times n$ matrices $A_n$ are uniformly bounded in absolute value. Let $u_n$ be defined by (2) and let $u_n$ denote a predictor for $u_n$. Suppose Assumptions 1 - 4 hold then:
(a) \( n^{-1} E |u_n' A_n u_n| = O(1), \ \text{var}(n^{-1} u_n' A_n u_n) = o(1) \) and
\[ n^{-1} \bar{u}'_n A_n \bar{u}_n - n^{-1} E \bar{u}'_n A_n u_n = o_p(1). \]

(b) \( n^{-1} E |d_{s,n}' A_n u_n| = O(1), \ s = 1, \ldots, p,\) where \( d_{s,n} \) denotes the \( s \)-th column of \( D_n \), and
\[ n^{-1} D_n' A_n \bar{u}_n - n^{-1} E D_n' A_n u_n = o_p(1). \]

(c) If furthermore Assumption 6 holds, then
\[ n^{-1/2} \bar{u}'_n A_n \bar{u}_n = n^{-1/2} u'_n A_n u_n + \alpha_n n^{1/2} \Delta_n + o_p(1) \]
with \( \alpha_n = n^{-1} ED_n' (A_n + A_n') u_n \). (Of course, in light of (b) we have \( \alpha_n = O(1) \) and \( n^{-1} D_n' (A_n + A_n') \bar{u}_n - \alpha_n = o_p(1) \).)

**Proof.** We first prove part (a) of the lemma. Let \( \vartheta_n = n^{-1} u_n' A_n u_n \) and \( \tilde{\vartheta}_n = n^{-1} \bar{u}'_n A_n \bar{u}_n \), then given (2) we have \( \vartheta_n = n^{-1} \epsilon_n' B_n \epsilon_n \) with
\[ B_n = (1/2) (I_n - \rho_n M_n)^{-1} (A_n + A_n') (I_n - \rho_n M_n)^{-1}. \]

By Assumption 3 the row and column sums of the matrices \( (I_n - \rho_n M_n)^{-1} \) are uniformly bounded in absolute value. Since this property is preserved under matrix addition and multiplication - see, e.g., Remark A.1 in Kelejian and Prucha (2004) - it follows that also the row and column sums of the matrices \( B_n \) are uniformly bounded in absolute value. Let \( \Sigma_n = \text{diag}(\sigma_{1,n}^2, \ldots, \sigma_{n,n}^2) \), then given Assumption 2 it follows further that also the row and column sums of the matrices \( B_n \Sigma_n B_n, \Sigma_n \) and \( B_n \Sigma_n B_n \Sigma_n \) are uniformly bounded in absolute value. In the following let \( K < \infty \) be a common bound for the row and column sums of the absolute elements of \( B_n, \Sigma_n \) and \( B_n \Sigma_n B_n, \Sigma_n \) and of their respective elements. Then
\[ E |\vartheta_n| = n^{-1} \sum_{i=1}^{n} \sum_{j=1}^{n} |b_{ij,n}| E |\epsilon_i| |\epsilon_j| \leq n^{-1} \sum_{i=1}^{n} \sum_{j=1}^{n} |b_{ij,n}| \sigma_{i,n} \sigma_{j,n} \leq K^3, \]

\[ \text{var}(\vartheta_n) = n^{-2} 2 \text{tr} (B_n \Sigma_n B_n \Sigma_n) + n^{-2} \sum_{i=1}^{n} b_{ii,n}^2 \left[ E \epsilon_i^4 - 3 \sigma_i^4 \right] \]
\[ \leq n^{-2} 2K + n^{-1} K^2 \sup_i \left[ E \epsilon_i^4 - 3 \sigma_i^4 \right], \]

where we utilized Lemma A.1. Given that the fourth moments of the \( \epsilon_{i,n} \) are uniformly bounded in light of Assumption 2 this establishes the first two claims of part (a) of the lemma.

We next prove the last claim of part (a) of the lemma. The above discussion implies that \( \vartheta_n - E \vartheta_n = o_p(1) \). Hence it suffices to show that \( \tilde{\vartheta}_n - \vartheta_n = o_p(1) \).

By Assumption 4 we have \( \bar{u}_n - u_n = D_n \Delta_n \) where \( D_n = [d_{1,n}' , \ldots, d_{n,n}']' \).

Utilizing this expression yields
\[ \tilde{\vartheta}_n - \vartheta_n = \phi_n + \psi_n \]

33
with
\[
\phi_n = n^{-1} \Delta_n' D_n' (A_n + A_n') u_n = n^{-1} \Delta_n' D_n' C_n \varepsilon_n,
\]
\[
\psi_n = n^{-1} \Delta_n' D_n' A_n D_n \Delta_n,
\]
and \( C_n = [c'_{1,n}, \ldots, c'_{r,n}]' = (A_n + A_n') (I_n - \rho_n M_n)^{-1} \). The row and column sums of the matrices \( C_n \) are again seen to be uniformly bounded in absolute value. Let \( K < \infty \) denote a uniform bound for the row and column sums of the absolute elements of the matrices \( A_n \) and \( C_n \).

To prove the claim we now show that both \( \phi_n \) and \( \psi_n \) are \( o_p(1) \). Using the triangle and Hölder inequality we get
\[
|\phi_n| = \left| n^{-1} \sum_{i=1}^n \Delta_n' d_{i,n}' c_{i,n} \varepsilon_n \right| 
\leq n^{-1} \| \Delta_n \| \sum_{i=1}^n \left| c_{i,j,n} \right| \| \varepsilon_{j,n} \| \leq n^{-1} \| \Delta_n \| \sum_{j=1}^n \| \varepsilon_{j,n} \| \sum_{i=1}^n \| d_{i,n} \| \left| c_{i,j,n} \right|
\leq n^{-1} \| \Delta_n \| \sum_{j=1}^n \| \varepsilon_{j,n} \| \left( \sum_{i=1}^n \| d_{i,n} \| \right)^{1/p} \left( \sum_{i=1}^n \left| c_{i,j,n} \right|^q \right)^{1/q}
\leq K n^{1/p-1/2} \left( n^{1/2} \| \Delta_n \| \right) \left( n^{-1} \sum_{j=1}^n \| \varepsilon_{j,n} \| \right) \left( n^{-1} \sum_{i=1}^n \| d_{i,n} \| \right)^{1/p}
\]
for \( p = 2 + \delta \) and \( 1/p + 1/q = 1 \), and where \( \delta > 0 \) is as in Assumption 4. The last inequality utilizes the observation of Remark C.1. Since the \( \varepsilon_{j,n} \) are independent with bounded second moments it follows that \( n^{-1} \sum_{j=1}^n \| \varepsilon_{j,n} \| = O_p(1) \). The terms \( n^{1/2} \| \Delta_n \| \) and \( n^{-1} \sum_{i=1}^n \| d_{i,n} \| \) are \( O_p(1) \) by Assumption 4. Since \( n^{1/p-1/2} \to 0 \) as \( n \to \infty \) it follows that \( \phi_n = o_p(1) \).

Again, using the triangle and Hölder inequality yields
\[
|\psi_n| = \left| n^{-1} \sum_{i=1}^n \sum_{j=1}^n \Delta_n' d_{i,n}' a_{i,j,n} d_{j,n} \Delta_n \right|
\leq n^{-1} \| \Delta_n \|^2 \sum_{i=1}^n \| d_{i,n} \| \sum_{j=1}^n \| d_{j,n} \| \| a_{i,j,n} \|
\leq n^{-1} \| \Delta_n \|^2 \sum_{i=1}^n \| d_{i,n} \| \left( \sum_{j=1}^n \| d_{j,n} \|^p \right)^{1/p} \left( \sum_{j=1}^n \| a_{i,j,n} \|^q \right)^{1/q}
\leq K n^{1/p} \| \Delta_n \|^2 \left( n^{-1} \sum_{i=1}^n \| d_{i,n} \| \right) \left( n^{-1} \sum_{j=1}^n \| d_{j,n} \|^p \right)^{1/p}
\leq K n^{1/p-1/2} n^{-1/2} (n^{1/2} \| \Delta_n \|)^2 \left( n^{-1} \sum_{i=1}^n \| d_{i,n} \|^p \right)^{2/p}
\]

34
with \( p \) and \( q \) as before. By Assumption 4 both \( n^{-1} \sum_{i=1}^{n} \|d_{i,n}\|^p \) and \( n^{1/2} \|\Delta_n\| \)
are \( O_p(1) \). Since \( n^{1/p-1/2} \rightarrow 0 \) as \( n \rightarrow \infty \) it follows that \( \psi_n = o_p(1) \). From the last inequality we see also that \( n^{1/2} \psi_n = o_p(1) \).

We next prove part (b) of the lemma. In the following let \( \vartheta_{s,n}^* \) denote the \( s \)-th element of \( n^{-1}D_n'\mathbf{A}_n u_n \). In light of the discussion after Assumption 3 and given Assumption 4 there exists a constant \( K < \infty \) such that \( Eu_{i,n}^2 \leq K \)
and \( E|d_{j,s,n}|^p \leq K \). W.l.o.g. assume that the row and column sums of the matrices \( \mathbf{A}_n \) are uniformly bounded by \( K \). Utilizing the Cauchy-Schwarz and Lyapunov inequalities we then have \( E|u_{i,n}| |d_{j,s,n}| \leq [Eu_{i,n}^2]^{1/2} [Ed_{j,s,n}^2]^{1/2} \leq [Eu_{i,n}^2]^{1/2} (E|d_{j,s,n}|^p)^{1/p} \leq K^{3/2+1/p} \) with \( p \) as before, and hence

\[
E|\vartheta_{s,n}^*| = n^{-1} \sum_{i=1}^{n} \sum_{j=1}^{n} |a_{i,j,n}| E|u_{i,n}| |d_{j,s,n}| \leq \frac{K^{3/2+1/p}}{n} \sum_{i=1}^{n} \sum_{j=1}^{n} |a_{i,j,n}| \leq \frac{K^{3/2+1/p}}{n} \leq \frac{K^{3/2+1/p}}{n} < \infty,
\]

which shows that indeed \( E|n^{-1}d_{s,n}'\mathbf{A}_n u_n| = O(1) \). Of course, the argument also shows that \( \alpha_n = n^{-1}ED_n'(\mathbf{A}_n + \mathbf{A}_n')u_n = O(1) \). Next observe that

\[
n^{-1}D_n'\mathbf{A}_n \tilde{u}_n = n^{-1}D_n'\mathbf{A}_n u_n + \phi_n^* \]

where \( \phi_n^* = n^{-1}D_n'\mathbf{A}_n D_n \Delta_n \). It now follows as a special case of our demonstration that \( \phi_n = o_p(1) \) that also \( \phi_n^* = o_p(1) \), which completes the proof of part (b).

We next prove part (c). In light of the proof of part (a) we have

\[
n^{-1/2}u_n'\mathbf{A}_n \tilde{u}_n = n^{-1/2}u_n'\mathbf{A}_n u_n + [n^{-1}u_n'(\mathbf{A}_n + \mathbf{A}_n')\mathbf{D}_n]n^{1/2} \Delta_n + n^{1/2} \psi_n \]

with \( n^{1/2} \psi_n = o_p(1) \). In light of part (b) we have \( n^{-1}u_n'(\mathbf{A}_n + \mathbf{A}_n')\mathbf{D}_n - \alpha_n' = o_p(1) \). The claim follows since \( n^{1/2} \Delta_n = O_p(1) \) by Assumption 4.

\( \blacksquare \)

Remark C.2: For future reference it proves helpful to note that in light of Remark A.1 in Kelejian and Prucha (2004) the constant \( K \) used in proving the last claim of part (a) of the above lemma can be chosen as \( K = 2cp\sqrt{c_A} \) where \( cp \) and \( c_A \) denote a bound for the row and column sums of the absolute elements of \( (\mathbf{I}_n - \rho_n \mathbf{M}_n)^{-1} \) and \( \mathbf{A}_n \). Furthermore it proves helpful to observe that in light of (C.1) and (C.2)

\[
|\vartheta_n - \vartheta_n| \leq 2cp\sqrt{c_A} \varsigma_n
\]

where \( \varsigma_n = o_p(1) \) does not depend on \( \mathbf{A}_n \).

Proof of Theorem 1: The existence and measurability of \( \tilde{\rho}_n \) is assured by, e.g., Lemma 3.4 in Pötscher and Prucha (1997). The objective function of the weighted nonlinear least squares estimator and its corresponding non-stochastic counterpart are given by, respectively,
To prove the consistency of \( \hat{\rho}_n \) we show that the conditions of, e.g., Lemma 3.1 in Pötscher and Prucha (1997) are satisfied for the problem at hand. We first show that \( \rho_n \) is an identifiably unique sequence of minimizers of \( \mathcal{R}_n \). Observe that \( \mathcal{R}_n(\rho) \geq 0 \) and that \( \mathcal{R}_n(\rho_n) = 0 \). From (6) we have \( \gamma_n = \Gamma_n[\rho_n, \rho_n^2]' \). Utilizing Assumption 5 we then get

\[
\mathcal{R}_n(\rho) - \mathcal{R}_n(\rho_n) = \mathcal{R}_n(\rho) = \left[ \rho - \rho_n, \rho^2 - \rho_n^2 \right] \Gamma_n' \Upsilon_n \Gamma_n \left[ \rho - \rho_n, \rho^2 - \rho_n^2 \right]' \\
\geq \lambda_{\min}(\Upsilon_n) \lambda_{\min}(\Gamma_n') \left[ \rho - \rho_n, \rho^2 - \rho_n^2 \right] \left[ \rho - \rho_n, \rho^2 - \rho_n^2 \right]' \\
\geq \lambda_* |\rho - \rho_n|^2
\]

for some \( \lambda_* > 0 \). Hence for every \( \varepsilon > 0 \) and \( n \) we have:

\[
\inf_{\{\rho \in [-a^p, a^p] : \|\rho - \rho_n\| \geq \varepsilon\}} \left| \mathcal{R}_n(\rho) - \mathcal{R}_n(\rho_n) \right| \\
\geq \inf_{\{\rho \in [-a^p, a^p] : \|\rho - \rho_n\| \geq \varepsilon\}} \lambda_* |\rho - \rho_n|^2 = \lambda_* \varepsilon^2 > 0,
\]

which proves that \( \rho_n \) is identifiably unique. Next let \( \Phi_n = [\Gamma_n, -\gamma_n] \) and \( \Phi_n = [\Gamma_n, -\gamma_n] \), then

\[
\left| R_n(\omega, \rho) - \mathcal{R}_n(\rho) \right| = \left| \left[ \rho, \rho^2, 1 \right] \left[ \Phi_n' \Upsilon_n \Phi_n - \Phi_n' \Upsilon_n \Phi_n \right] \left[ \rho, \rho^2, 1 \right]' \right| \\
\leq \left\| \Phi_n' \Upsilon_n \Phi_n - \Phi_n' \Upsilon_n \Phi_n \right\| \left\| \left[ \rho, \rho^2, 1 \right] \right\|^2 \\
\leq \left\| \Phi_n' \Upsilon_n \Phi_n - \Phi_n' \Upsilon_n \Phi_n \right\| \left[ 1 + (a^p)^2 + (a^p)^4 \right].
\]

As is readily seen from the respective second expressions on the r.h.s. of (7), the elements of \( \Phi_n \) and \( \Phi_n \) are all of the form \( n^{-1} E u_n \mathbf{A}_n u_n \) and \( n^{-1} \tilde{u}_n \mathbf{A}_n \tilde{u}_n \) where the row and column sums of \( \mathbf{A}_n \) are bounded uniformly in absolute value. It now follows immediately from Lemma C.1 that \( \Phi_n - \Phi_n \overset{p}{\to} 0 \), and that the elements of \( \Phi_n \) and \( \Phi_n \) are, respectively, \( O_p(1) \) and \( O(1) \). The analogous properties are seen to hold for the elements of \( \Upsilon_n \) and \( \Upsilon_n \) in light of Assumption 5. Given this it follows from the above inequality that \( R_n(\omega, \rho) - \mathcal{R}_n(\rho) \) converges to zero uniformly over the optimization space \([a^p, a^p]\), i.e.,

\[
\sup_{\rho \in [-a^p, a^p]} \left| R_n(\omega, \rho) - \mathcal{R}_n(\rho) \right| \leq \left\| \Phi_n' \Upsilon_n \Phi_n - \Phi_n' \Upsilon_n \Phi_n \right\| \left[ 1 + (a^p)^2 + (a^p)^4 \right] \overset{p}{\to} 0
\]

36
as \( n \to \infty \). The consistency of \( \hat{\rho}_n \) now follows directly from Lemma 3.1 in Pötscher and Prucha (1997).

We make use of the following lemma.

**Lemma C.2**: Let \( u_n \) be defined by (2) and let \( D_n = [d'_{1,n}, \ldots, d'_{n,n}]' \), where \( d_{i,n} \) is defined in Assumption 4. Suppose Assumptions 1 - 3 hold, and suppose furthermore that the columns of \( D_n \) are of the form \( \pi_n + \Pi_n \varepsilon_n \), where the elements of \( \pi_n \) are bounded in absolute value and the row and column sums of \( \Pi_n \) are uniformly bounded in absolute value. Then (a) \( Ed_{i,n}^4 \leq \text{const} < \infty \), and thus the moment condition in Assumption 4 is automatically implied, and (b) Assumption 6 is automatically implied.

**Proof.** Observe that for the fourth moment of the \( i \)-th element of \( \pi_n + \Pi_n \varepsilon_n \) we have

\[
E(\pi_{i,n} + \sum_{j=1}^{n} \pi_{ij,n} \varepsilon_{j,n})^4 \leq 2^4 \left[ \pi_i^4 + E \left( \sum_{j=1}^{n} \pi_{ij,n} \varepsilon_{j,n} \right)^4 \right] \leq 2^4 \left[ \pi_i^4 + \sum_{j=1}^{n} \sum_{k=1}^{n} \sum_{l=1}^{n} \sum_{m=1}^{n} |\pi_{ij,n}| |\pi_{ik,n}| |\pi_{il,n}| |\pi_{im,n}| E |\varepsilon_{j,n}| |\varepsilon_{k,n}| |\varepsilon_{l,n}| |\varepsilon_{m,n}| \right] \leq \text{const} < \infty
\]

since by assumption the elements of \( \pi_n \) are bounded in absolute value and the row and column sums of \( \Pi_n \) are uniformly bounded in absolute value, and since \( E |\varepsilon_{j,n}| |\varepsilon_{k,n}| |\varepsilon_{l,n}| |\varepsilon_{m,n}| \) is uniformly bounded in light of Assumption 2. This proves claim (a).

Given the maintained assumptions of the lemma and utilizing (3) the elements of \( n^{-1}D_n'u_nu_n' \) are seen to be of the form

\[
\chi_n = n^{-1}b_{i,n}' \varepsilon_n + n^{-1}e_{i,n}' B_n^* \varepsilon_n
\]

where \( b_{i,n}' = \pi_n'A_n (I_n - \rho_n M_n)^{-1} \) and \( B_n^* = \Pi_n'A_n (I_n - \rho_n M_n)^{-1} \). Given Remark A.1 in Kelejian and Prucha (2004) the elements of \( b_{i,n}' \) are seen to be bounded and the rows and column sums of \( B_n^* \) are seen to be uniformly bounded in absolute value. By arguments analogous to those in the proof of Lemma C.1 it then readily seen that \( E\chi_n = O(1) \) and \( \text{var}(\chi_n) = o(1) \). Claim (b) now follows from Chebychev’s inequality.

**Proof of Theorem 2**: Define

\[
q_n(\rho_n, \Delta_n) = \tilde{\gamma}_n - \tilde{\Gamma}_n \begin{bmatrix} \rho_n \\ \rho_n^2 \end{bmatrix} = \begin{bmatrix} n^{-1} \tilde{u}'_{1,n} C_{1,n} \tilde{u}_n \\ n^{-1} \tilde{u}'_{2,n} C_{2,n} \tilde{u}_n \end{bmatrix}
\]

with \( C_{r,n} = (1/2) (I_n - \rho_n M_n^*) (A_{r,n} + A_{r,n}^*) (I_n - \rho_n M_n) \), and where the matrices \( A_{r,n} \) are defined by (5), \( r = 1, 2 \). The second equality in (C.3) is seen to hold in light of the discussion surrounding equations (4)-(9). For later use
we observe that the rows and column sums of $\mathbf{C}_{r,n}$ are uniformly bounded in absolute value; see, e.g., Remark A.1 in Kelejian and Prucha (2004).

We have shown in Theorem 1 that the GM estimator $\hat{\rho}_n$ defined in (9) is consistent. Apart on a set whose probability tends to zero the estimator satisfies the following first order condition

$$q_n(\hat{\rho}_n, \Delta_n)' \tilde{\mathbf{Y}}_n \frac{\partial q_n(\hat{\rho}_n, \Delta_n)}{\partial \rho} = 0.$$  

Substituting the mean value theorem expression

$$q_n(\hat{\rho}_n, \Delta_n) = q_n(\rho_n, \Delta_n) + \frac{\partial q_n(\hat{\rho}_n, \Delta_n)}{\partial \rho} (\hat{\rho}_n - \rho_n)$$

into the first order condition yields

$$\frac{\partial q_n(\hat{\rho}_n, \Delta_n)}{\partial \rho'} \tilde{\mathbf{Y}}_n \frac{\partial q_n(\hat{\rho}_n, \Delta_n)}{\partial \rho} n^{1/2} (\hat{\rho}_n - \rho_n) = -\frac{\partial q_n(\hat{\rho}_n, \Delta_n)}{\partial \rho} \tilde{\mathbf{Y}}_n n^{1/2} q_n(\rho_n, \Delta_n)$$

where $\tilde{\mathbf{Y}}_n$ is some between value. Observe that

$$\frac{\partial q_n(\rho_n, \Delta_n)}{\partial \rho} = -\tilde{\mathbf{Y}}_n \left[ \begin{array}{c} 1 \\ 2\rho_n \end{array} \right]$$

and consider the nonnegative scalars

$$\mathbf{\Xi}_n = \frac{\partial q_n(\hat{\rho}_n, \Delta_n)}{\partial \rho'} \tilde{\mathbf{Y}}_n \frac{\partial q_n(\hat{\rho}_n, \Delta_n)}{\partial \rho} = \left[ \begin{array}{c} \frac{1}{2\rho_n} \\ \tilde{\mathbf{Y}}_n \tilde{\mathbf{Y}}_n \end{array} \right] \left[ \begin{array}{c} 1 \\ 2\rho_n \end{array} \right],$$

$$\mathbf{\Xi}_n = \left[ \begin{array}{c} 1 \\ 2\rho_n \end{array} \right] \tilde{\mathbf{Y}}_n \tilde{\mathbf{Y}}_n \left[ \begin{array}{c} 1 \\ 2\rho_n \end{array} \right].$$

In proving Theorem 1 we have demonstrated that $\tilde{\mathbf{Y}}_n - \mathbf{Y}_n \equiv 0$ and that the elements of $\mathbf{\Gamma}_n$ and $\mathbf{\Gamma}_n$ are $O_p(1)$ and $O(1)$, respectively. By Assumption 5 we have $\tilde{\mathbf{Y}}_n - \mathbf{Y}_n = o_p(1)$ and also that the elements of $\tilde{\mathbf{Y}}_n$ and $\mathbf{Y}_n$ are $O_p(1)$ and $O(1)$, respectively. Since $\hat{\rho}_n$ and $\tilde{\mathbf{Y}}_n$ are consistent and bounded in absolute value, clearly

$$\mathbf{\Xi}_n - \mathbf{\Xi}_n \equiv 0$$

as $n \to \infty$, and furthermore $\mathbf{\Xi}_n = O_p(1)$ and $\mathbf{\Xi}_n = O(1)$. In particular $\mathbf{\Xi}_n \leq \lambda_{\Xi}^*$ where $\lambda_{\Xi}^*$ is some finite constant. In light of Assumption 5 we have $\mathbf{\Xi}_n \geq \lambda_{\min}(\mathbf{Y}_n)\lambda_{\min}(\mathbf{\Gamma}_n^2\mathbf{\Gamma}_n)(1+4\rho_n^2) \geq \lambda_{\Xi}^*$ for some $\lambda_{\Xi}^* > 0$. Hence $0 < \mathbf{\Xi}_n^{-1} \leq 1/\lambda_{\Xi}^* < \infty$, and thus we also have $\mathbf{\Xi}_n^{-1} = O(1)$. Let $\mathbf{\Xi}_n^{-1}$ denote the generalized inverse of $\mathbf{\Xi}_n$. It then follows as a special case of Lemma F1 in Pötscher and Prucha (1997) that $\mathbf{\Xi}_n$ is nonsingular eventually with probability tending to one, that $\mathbf{\Xi}_n = O_p(1)$, and that

$$\mathbf{\Xi}_n^{-1} - \mathbf{\Xi}_n^{-1} \equiv 0$$
as $n \to \infty$.

Premultiplying (C.4) by $\tilde{\Sigma}_n^+$ and rearranging terms yields

$$
n^{1/2}(\tilde{\rho}_n - \rho_n) = \left[ 1 - \tilde{\Sigma}_n^+ \tilde{\Sigma}_n \right] n^{1/2}(\tilde{\rho}_n - \rho_n) - \tilde{\Sigma}_n^+ \frac{\partial q_n(\tilde{\rho}_n, \Delta_n)}{\partial \rho} \tilde{\Sigma}_n n^{1/2} q_n(\rho_n, \Delta_n).
$$

In light of the above discussion the first term on the r.h.s. is zero on $\omega$-sets of probability tending to one. This yields

$$
n^{1/2}(\tilde{\rho}_n - \rho_n) = -\tilde{\Sigma}_n^+ \frac{\partial q_n(\tilde{\rho}_n, \Delta_n)}{\partial \rho} \tilde{\Sigma}_n n^{1/2} q_n(\rho_n, \Delta_n) + o_p(1). \quad (C.9)
$$

Observe that

$$
\tilde{\Sigma}_n^+ \frac{\partial q_n(\tilde{\rho}_n, \Delta_n)}{\partial \rho} \tilde{\Sigma}_n n^{1/2} q_n(\rho_n, \Delta_n) = \tilde{\Sigma}_n^{-1} \left( \frac{1}{2\rho_n} \right)' \Gamma_n^{-1} \Gamma_n = o_p(1).
$$

(C.10)

In light of (C.3) and Lemma C.1 the elements of $n^{1/2} q_n(\rho_n, \Delta_n)$ can be expressed as $(r = 1, 2)$

$$
n^{-1/2} \tilde{u}_n C_{r,n} \tilde{u}_n = n^{-1/2} u_n' C_{r,n} u_n + \alpha_{r,n} n^{1/2} \Delta_n + o_p(1)
$$

where

$$
\alpha_{r,n} = 2n^{-1} E \tilde{D}_n' C_{r,n} u_n.
$$

Furthermore, the lemma implies that the elements of $\alpha_{r,n}$ are uniformly bounded in absolute value. Utilizing $u_n = (I_n - \rho_n M_n)^{-1} \varepsilon_n$ and Assumption 7 we have

$$
n^{1/2} q_n(\rho_n, \Delta_n) = n^{-1/2} \left[ \frac{1}{2} \varepsilon_n'(A_{1,n} + A_{1,n}') \varepsilon_n + a_{1,n}' \varepsilon_n + a_{1,n}' \varepsilon_n \right] + o_p(1) \quad (C.11)
$$

where $a_{r,n} = T_n \alpha_{r,n}$, $r = 1, 2$. Observe that the elements of $a_{r,n}$ are uniformly bounded in absolute value. As discussed before Theorem 2 in the text, the VC matrix of the vector of quadratic forms on the r.h.s. of (C.11) is given by $\Psi_n$ where the elements of that matrix are given in (13). Those elements can be written more explicitly as

$$
\psi_{rs,n} = \frac{1}{2n} \sum_{i=1}^{n} \sum_{j=1}^{n} (a_{ij,r,n} + a_{ji,r,n})(a_{ij,s,n} + a_{ji,s,n}) \sigma^2_{i,n} \sigma^2_{j,n} + \frac{1}{n} \sum_{i=1}^{n} a_{i,r,n} a_{i,s,n} \sigma^2_{i,n} \quad (C.12)
$$

By assumption $\lambda_{\min}(\Psi_n) \geq \text{const} > 0$. Since the matrices $A_{r,n}$, the vectors $a_{r,n}$, and the innovations $\varepsilon_n$ satisfy all of the remaining assumptions of the central limit theorem for vectors of linear quadratic forms given above as Theorem A.1 it follows that

$$
\xi_n = -\Psi_n^{-1/2} n^{-1/2} \left[ \frac{1}{2} \varepsilon_n'(A_{1,n} + A_{1,n}') \varepsilon_n + a_{1,n}' \varepsilon_n \right] \Rightarrow N(0, I_2).
$$

(C.13)

Since the row and column sums of the matrices $A_{r,n}$ are uniformly bounded in absolute value, and since the elements of $a_{r,n}$ and the variances are uniformly
bounded by finite constants it is readily seen from (C.12) that the elements of \( \Psi_n \), and hence those of \( \Psi_n^{1/2} \) are uniformly bounded. It now follows from (C.9), (C.10) and (C.13) that

\[
n^{-1/2}(\rho_n - \rho_n) = \Xi_n^{-1} \left[ \frac{1}{2\rho_n} \Gamma_n \Psi_n^{1/2} \xi_n + o_p(1) \right]. \tag{C.14}
\]

Observing that \( \Xi_n = J_n \Psi_n J_n \), where \( J_n = \Gamma_n[1, 2\rho_n] \), this establishes (14). Since all of the nonstochastic terms on the r.h.s. of (C.14) are \( O(1) \) it follows that \( n^{1/2}(\rho_n - \rho_n) = O_p(1) \). Next recall that \( 0 < \lambda_{\Xi}^* \leq \Xi_n \leq \lambda_{\Xi}^* < \infty \). Hence

\[
\Xi_n^{-1} J_n \Psi_n J_n \Xi_n^{-1} \geq \lambda_{\min}(\Psi_n) \left| \lambda_{\min}(\Gamma_n) \right|^2 \lambda_{\min}(\Gamma_n) \Gamma_n(1 + 4\rho_n^2)/1(\lambda_{\Xi}^* \lambda_{\Xi}^*)^2 \geq const > 0.
\]

This establishes the last claim of the theorem.

As part of proving Theorem 3 will be to show that \( \tilde{\Psi}_n - \Psi_n = o_p(1) \). Observe that the elements can be written as

\[
\tilde{\psi}_{rs,n} = \psi_{rs,n} + \tilde{\psi}_{rs,n}^*, \quad \text{and} \quad \psi_{rs,n} = \psi_{rs,n}^* + \psi_{rs,n}^{**} \tag{C.15}
\]

with

\[
\psi_{rs,n}^* = (2n)^{-1} \sum_{i=1}^{n} \sum_{j=1}^{n} a_{ij,n} \epsilon_{i,n}^2 \epsilon_{j,n}, \quad \psi_{rs,n} = (2n)^{-1} \sum_{i=1}^{n} \sum_{j=1}^{n} a_{ij,n} \sigma_{i,n}^2 \sigma_{j,n}, \quad \tilde{\psi}_{rs,n}^* = (2n)^{-1} \sum_{i=1}^{n} \sum_{j=1}^{n} a_{ij,n} \alpha_{i,n}^2 \alpha_{j,n}, \quad \psi_{rs,n}^{**} = n^{-1} \alpha_{r,n} \psi_{n} F_n \Sigma_n F_n P_n \alpha_{s,n}, \tag{C.16}
\]

where \( a_{ij,n} = (a_{ij,r,n} + a_{ij,s,n})(a_{ij,r,n} + a_{ij,s,n}) \).

The next two lemmata will be used to show that \( \tilde{\psi}_{rs,n} - \psi_{rs,n} = o_p(1) \).

**Lemma C.3**: Suppose Assumptions 1 - 3 hold. Let \( \Lambda_n = n^{-1}(\sigma_n^2)' A_n \sigma_n^2 \) and \( \Lambda_n = n^{-1}(\epsilon_n^2)' A_n \epsilon_n^2 \) with \( \sigma_n^2 = (\sigma_1^2, \ldots, \sigma_n^2)' \) and \( \epsilon_n^2 = (\epsilon_1^2, \ldots, \epsilon_n^2)' \), and where the \( n \times n \) matrices \( A_n \) are real nonstochastic and symmetric. Suppose further that the diagonal elements of the matrices \( A_n \) are zero and that their row and column sums are uniformly bounded in absolute value. Then \( E\Lambda_n = \Lambda_n \) and \( \text{var}(\Lambda_n) = O(1) \), and hence \( \Lambda_n - \Lambda_n \overset{\text{P}}{\rightarrow} 0 \) as \( n \rightarrow \infty \), and \( \Lambda_n \overset{O_p}{=} 0 \).

**Proof.** Observe that

\[
\Lambda_n = n^{-1} \sum_{i=1}^{n} \sum_{j=1}^{n} a_{ij,n} \epsilon_{i,n}^2 \epsilon_{j,n}, \tag{C.17}
\]

\[
\Lambda_n = n^{-1} \sum_{i=1}^{n} \sum_{j=1}^{n} a_{ij,n} \sigma_{i,n}^2 \sigma_{j,n}.
\]

Since \( a_{ii,n} = 0 \) and the innovations \( \epsilon_{i,n} \) are assumed to be independent, clearly \( E\Xi_n = \Lambda_n \). The claim that \( \Lambda_n = O(1) \) follows from the triangle inequality, observing that the variances \( \epsilon_{i,n}^2 \) are uniformly bounded and that furthermore also the row and column sums of the matrices \( A_n \) are uniformly

40
bounded in absolute value. Define \( \zeta_n = \varepsilon_n^2 - \sigma_n^2 \), then \( \zeta_n \sim (0, \Xi_n) \) where \( \Xi_n = \text{diag}_{i=1}^n [E(\varepsilon_{i,n}^2) - \sigma_{i,n}^2] \). Clearly

\[
\overline{\Lambda}_n = \Lambda_n + n^{-1} \zeta_n A_n \zeta_n + 2n^{-1}(\sigma_n^2)\Lambda_n A_n \zeta_n.
\]

It now follows from Lemma A.1 that

\[
\text{var}(\overline{\Lambda}_n) = 2n^{-2}tr [A_n \Xi_n A_n \Xi_n] + 4n^{-2}(\sigma_n^2)\Lambda_n \Xi_n A_n \zeta_n.
\]

Given the maintained assumptions it follows, e.g., from Remark A.1 in Kelejian and Prucha (2004) that the row and column sums of \( A_n \Xi_n A_n \) and \( A_n \Xi_n A_n \) are uniformly bounded in absolute value. Given that the variances \( \sigma_n^2 \) are uniformly bounded it follows that \( \text{var}(\overline{\Lambda}_n) = o(1) \). Hence by Chebychev’s inequality \( \overline{\Lambda}_n - \Lambda_n = o_p(1) \). The last claim is now obvious.

\[\text{Lemma C.4} : \text{Suppose Assumptions 1 - 4 hold. Let } \varepsilon_n = (I_n - \rho_n M_n) u_n, \text{ and let } \bar{\varepsilon}_n = (I_n - \bar{\rho}_n M_n) \bar{u}_n \text{ with } \bar{u}_n = u_n + D_n \Delta_n \text{ and } D_n = [d_{1,n}, \ldots, d_{n,n}'], \text{ and where } \bar{\rho}_n \text{ can be any estimator that satisfies } n^{1/2}(\bar{\rho}_n - \rho_n) = O_p(1). \text{ Define } \tilde{\Lambda}_n = n^{-1}(\bar{\varepsilon}_n^2 A_n \bar{\varepsilon}_n^2), \overline{\Lambda}_n = n^{-1}(\bar{\varepsilon}_n^2)^\prime A_n \bar{\varepsilon}_n^2 \text{ with } \bar{\varepsilon}_n^2 = (\bar{\varepsilon}_{1,n}^2, \ldots, \bar{\varepsilon}_{n,n}^2)', \bar{\varepsilon}_n^2 = (\varepsilon_{1,n}^2, \ldots, \varepsilon_{n,n}^2)', \text{ and where the } n \times n \text{ matrices } A_n \text{ are real nonstochastic and symmetric. Suppose further that the diagonal elements of the matrices } A_n \text{ are zero and that their row and column sums are uniformly bounded in absolute value, and that } Ed_{i,j,n}^4 \leq K_d < \infty. \text{ Then, } \overline{\Lambda}_n - \tilde{\Lambda}_n \xrightarrow{p} 0 \text{ as } n \to \infty, \text{ and } \overline{\Lambda}_n = O_p(1). \]

\[\text{Proof.} \text{ Observe that } \overline{\Lambda}_n - \tilde{\Lambda}_n = \psi_{1n} + \psi_{2n} + \psi_{3n} \quad (C.18)
\]

where

\[
\psi_{1n} = n^{-1} \sum_{i=1}^n \sum_{j=1}^n a_{i,j,n} \left[ \bar{\varepsilon}_{i,n}^2 - \varepsilon_{i,n}^2, \bar{\varepsilon}_{j,n}^2 - \varepsilon_{j,n}^2 \right],
\]

\[
\psi_{2n} = n^{-1} \sum_{i=1}^n \sum_{j=1}^n a_{i,j,n} \left[ \bar{\varepsilon}_{i,n}^2 - \varepsilon_{i,n}^2, \bar{\varepsilon}_{j,n}^2 - \varepsilon_{j,n}^2 \right],
\]

\[
\psi_{3n} = n^{-1} \sum_{i=1}^n \sum_{j=1}^n a_{i,j,n} \left[ \bar{\varepsilon}_{i,n}^2 - \varepsilon_{i,n}^2, \bar{\varepsilon}_{j,n}^2 - \varepsilon_{j,n}^2 \right].
\]

Observe that

\[
\bar{\varepsilon}_n = (I_n - \bar{\rho}_n M_n) \bar{u}_n = (I_n - \bar{\rho}_n M_n) (u_n + D_n \Delta_n) \quad (C.20)
\]

\[= \varepsilon_n + (I_n - \rho_n M_n) D_n \Delta_n - (\bar{\rho}_n - \rho_n) M_n u_n - (\bar{\rho}_n - \rho_n) M_n D_n \Delta_n
\]

\[= \varepsilon_n + \eta_n
\]
In light of Assumptions 3 and since the elements of $\gamma \geq \xi$ Remark C.1 it then follows that the columns of $R_n$ and $\varepsilon_n$ have bounded fourth moments it follows that the columns of $R_n$ and $\varepsilon_n$ are all of the form $\pi_n + \Pi_n \xi_n$, where the elements of the $n \times 1$ vector $\pi_n$ are uniformly bounded in absolute value by some finite constant, where the row and column sums of the $n \times n$ matrix $\Pi_n$ are uniformly bounded in absolute value by some finite constant, and where the fourth moments of the elements of $\xi_n$ are also bounded by some finite constant. In light of this it is easily seen that the fourth moments of the elements of $R_n$ are bounded by some finite constant. Consequently

$$|\eta_{i,n}| \leq \alpha_n \beta_{i,n} \tag{C.21}$$

where $\alpha_n = \| \Delta_i, (\rho_n - \tilde{\rho}_n), (\rho_n - \tilde{\rho}_n) \Delta_i' \|$ and $\beta_{i,n} = \| r_i, n \|$ with $E \beta_{i,n}^4 \leq K_\beta$ where $K_\beta$ is some finite constant. Of course, w.o.l.g., we can select $K_\beta$ such that $E \beta_{i,n}^4 \leq K_\beta$ for $\gamma \leq 4$. Observe furthermore that in light of the maintained assumptions $n^{1/2} \alpha_n = O_p(1)$. Given Assumption 2 we have: $E |\xi_{i,n}|^\gamma \leq K_\varepsilon$, $\gamma \leq 4 + \eta$, for some $K_\varepsilon < \infty$. By the assumptions of the lemma $\sum_{i=1}^n |a_{i,n}| < K_a$ for some $K_a < \infty$. In the following let $K = \max\{1, K_a K_\varepsilon, K_\xi\}$. In light of Remark C.1 it then follows that $\sum_{i=1}^n |a_{i,n}|^\gamma < K^\gamma$ and $\sum_{i=1}^n |b_{i,n}|^\gamma < K^\gamma$ for $\gamma \geq 1$.

From (C.20) and (C.21) we have

$$|\varepsilon_{i,n}^2 - \varepsilon_{i,n}^2| = |2 \varepsilon_{i,n} \eta_{i,n} + \eta_{i,n}^2| \leq 2 \alpha_n \beta_{i,n} \varepsilon_{i,n}^2 + \alpha_n^2 \beta_{i,n}^2 \tag{C.22}$$

Applying the triangle inequality to the first equation of (C.19) and making use of (C.22) yields

$$|\psi_{i,n}| \leq 2 \alpha_n n^{-1} \sum_{i=1}^n \beta_{i,n} \varepsilon_{i,n}^2 \sum_{j=1}^n |a_{i,j,n}| \varepsilon_{j,n}^2 \quad \text{+} \quad \alpha_n^2 n^{-1} \sum_{i=1}^n \beta_{i,n}^2 \sum_{j=1}^n |a_{i,j,n}| \varepsilon_{j,n}^2 \leq \delta_{i,n}^* + \delta_{i,n}^{**} \tag{C.23}$$

$$\delta_{i,n}^* = 2 Kn^{1/2-1/2}(n^{1/2} \alpha_n)^2 \zeta_n \left[ n^{-1} \sum_{i=1}^n \beta_{i,n} \varepsilon_{i,n}^2 \right],$$

$$\delta_{i,n}^{**} = Kn^{1/2-1/2}(n^{1/2} \alpha_n)^2 \zeta_n \left[ n^{-1} \sum_{i=1}^n \beta_{i,n}^2 \right].$$

where $\zeta_n = \left[ n^{-1} \sum_{j=1}^n |a_{i,j,n}|^4 + \eta \right]^{1/r}$ with $r = 2 + \eta/2$. In obtaining the above result we also utilized that by Hölder’s inequality $\sum_{j=1}^n |a_{i,j,n}| \varepsilon_{j,n}^2 \leq n^{1/r} K \zeta_n$.\[42\]
hence also the terms in square brackets in (C.23) tend to zero as \( n \rightarrow \infty \). Therefore we have \( \delta_{3n}^* = o_p(1) \) and \( \delta_{3n}^{**} = o_p(1) \) and hence \( \psi_{1n} = o_p(1) \). Because of symmetry it follows that also \( \psi_{2n} = o_p(1) \).

Applying the triangle inequality to the last equation of (C.19) and making use of (C.22) yields

\[
|\psi_{3n}| \leq 4\alpha_n^2 n^{-1} \sum_{i=1}^{n} \beta_{i,n} \varepsilon_{i,n} \sum_{j=1}^{n} |a_{ij,n}| \beta_{j,n} |\varepsilon_{j,n}| \tag{C.24}
\]

\[
+ 2\alpha_n^4 n^{-1} \sum_{i=1}^{n} \beta_{i,n} \varepsilon_{i,n} \sum_{j=1}^{n} |a_{ij,n}|(\beta_{j,n}^2 + 2\alpha_n^2 \beta_{j,n} \varepsilon_{j,n}) + 2\alpha_n^4 n^{-1} \sum_{i,j=1}^{n} \beta_{i,n} \varepsilon_{i,n} \sum_{i=1}^{n} |a_{ij,n}| \beta_{i,n}^2 \\
+ \alpha_n^4 n^{-1} \sum_{i=1}^{n} \beta_{i,n}^2 \sum_{j=1}^{n} |a_{ij,n}| \beta_{j,n}^2 \leq \delta_{3n}^* + \delta_{3n}^{**} + \delta_{3n}^{***}
\]

\[
\delta_{3n}^* = 4Kn^{1/2-1}(n^{1/2} \alpha_n)^2 \zeta_n \left[ n^{-1} \sum_{i=1}^{n} \beta_{i,n} \varepsilon_{i,n} \right]
\]

\[
\delta_{3n}^{**} = 4Kn^{-1}(n^{1/2} \alpha_n)^2 \zeta_n \left[ n^{-1} \sum_{i=1}^{n} \beta_{i,n} \varepsilon_{i,n} \right]
\]

\[
\delta_{3n}^{***} = Kn^{-3/2}(n^{1/2} \alpha_n)^2 \zeta_n \left[ n^{-1} \sum_{i=1}^{n} \beta_{i,n}^2 \right]
\]

where \( \zeta_n = \left[ n^{-1} \sum_{j=1}^{n} \beta_{j,n}^2 n^{-1} \sum_{j=1}^{n} \beta_{j,n}^2 \right]^{1/2} \) and \( \zeta_n = \left[ n^{-1} \sum_{j=1}^{n} \beta_{j,n}^4 \right]^{1/2} \). In obtaining the above result we also utilized that by H"{o}lder’s inequality \( \sum_{j=1}^{n} |a_{ij,n}| \beta_{j,n} \varepsilon_{j,n} \leq n^{1/2} \sum_{j=1}^{n} \beta_{j,n} \varepsilon_{j,n} \) and \( \sum_{i=1}^{n} |a_{ij,n}| \beta_{i,n} \varepsilon_{i,n} \leq n^{1/2} \sum_{i=1}^{n} \beta_{i,n} \varepsilon_{i,n} \). Since \( E \beta_{j,n}^2 \varepsilon_{j,n} \leq [E \beta_{j,n}^2 E \varepsilon_{j,n}^2]^{1/2} \leq K \) and \( E \beta_{j,n}^4 \leq K \) it follows that \( \zeta_n = o_p(1) \) and \( \zeta_n = o_p(1) \). Since \( E \beta_{i,n} \varepsilon_{i,n} \leq [E \beta_{i,n}^2 E \varepsilon_{i,n}^2]^{1/2} \leq K \) all terms in square brackets in (C.24) are seen to be \( o_p(1) \). Observing that \( n^{1/2} \alpha_n = o_p(1) \) it follows that \( \delta_{3n}^* = o_p(1) \), \( \delta_{3n}^{**} = o_p(1) \), \( \delta_{3n}^{***} = o_p(1) \) and hence \( \psi_{3n} = o_p(1) \). This proves that \( \overline{\Lambda}_n - \underline{\Lambda}_n \rightarrow 0 \). The last claim follows trivially since by Lemma C.3 \( \overline{\Lambda}_n = o_p(1) \).

The next two lemmata will be used to show that \( \tilde{\psi}_{rs,n} - \psi_{rs,n} = o_p(1) \), where \( \tilde{\psi}_{rs,n} \) and \( \psi_{rs,n} \) are defined in (C.15) and (C.16).

**Lemma C.5**: Suppose Assumptions 1 - 4 hold. Let \( \varepsilon_n = (I_n - \rho_n M_n) u_n \), and let \( \overline{\varepsilon}_n = (I_n - \rho_n \Delta_n) \overline{u}_n \) with \( \overline{u}_n = u_n + D_n \Delta_n \) and \( D_n = [d_{1,n}, \ldots, d_{4,n}]' \), and where \( \rho_n \) can be any estimator that satisfies \( |\rho_n - \rho_n| = o_p(1) \). Let \( a_n \) and
\( \mathbf{b}_n \) be \( n \times 1 \) vectors whose elements are uniformly bounded in absolute value by \( c < \infty \) and let \( \Sigma_n = \text{diag}_{i=1,...,n}(\alpha_i^2) \) and \( \hat{\Sigma}_n = \text{diag}_{i=1,...,n}(\hat{\alpha}_i^2) \). Then:

(a) \( n^{-1} \mathbf{a}'_n \hat{\Sigma}_n \mathbf{b}_n - n^{-1} \mathbf{a}'_n \Sigma_n \mathbf{b}_n = o_p(1) \) and \( n^{-1} \mathbf{a}'_n \Sigma_n \mathbf{b}_n = O(1) \).

(b) There exist random variables \( \zeta_n \) that do not depend on \( \mathbf{a}_n \) and \( \mathbf{b}_n \) such that

\[
\left| n^{-1} \mathbf{a}'_n \hat{\Sigma}_n \mathbf{b}_n - n^{-1} \mathbf{a}'_n \Sigma_n \mathbf{b}_n \right| \leq K(c)(1 + \zeta_n)
\]

with \( \zeta_n = o_p(1) \) and where \( K(c) < \infty \) is a constant that depends monotonically on \( c \) (as well as on other bounds maintained in the assumptions).

**Proof.** Let \( \tilde{\tau}_n = n^{-1} \mathbf{a}'_n \hat{\Sigma}_n \mathbf{b}_n \) and \( \tau_n = n^{-1} \mathbf{a}'_n \Sigma_n \mathbf{b}_n \). We furthermore define \( \tau_n = n^{-1} \mathbf{a}'_n \Sigma_n \mathbf{b}_n \) where \( \Sigma_n = \text{diag}_{i=1,...,n}(\alpha_i^2) \). Clearly

\[
|\tilde{\tau}_n - \tau_n| \leq |\tilde{\tau}_n - \tau_n| + |\tau_n - \tau_n|.
\]

By the weak law of large numbers for i.d. random variables, observing that the fourth moments of \( \varepsilon_{i,n} \) are uniformly bounded, we have

\[
\tau_n - \tau_n = n^{-1} \sum_{i=1}^n a_{i,n} b_{i,n} \left( \varepsilon_{i,n}^2 - \sigma_{i,n}^2 \right) = o_p(1)
\]

and thus \( |	au_n - \tau_n| = o_p(1) \). Next let

\[
\zeta_{1,n} = n^{-1} \sum_{i=1}^n \left( |\varepsilon_{i,n}^2 - \sigma_{i,n}^2| - E|\varepsilon_{i,n}^2 - \sigma_{i,n}^2| \right)
\]

and \( c_\ast \) be such that \( \sigma_{i,n}^2 \leq c_\ast \), then using the triangle inequality several times, it is readily seen

\[
|\tau_n - \tau_n| \leq c^2 \zeta_{1,n} + 2c^2 c_\ast.
\]

Again by the weak law of large numbers for i.d. random variables we have \( \zeta_{1,n} = o_p(1) \).

It proves convenient to rewrite \( \tilde{\tau}_n \) and \( \tau_n \) as

\[
\tilde{\tau}_n = n^{-1} \mathbf{a}'_n \mathbf{C}_n \mathbf{e}_n = n^{-1} \mathbf{u}'_n \mathbf{C}_n \mathbf{u}_n - 2\rho_n n^{-1} \mathbf{u}'_n \mathbf{M}'_n \mathbf{C}_n \mathbf{u}_n + \rho_n n^{-1} \mathbf{u}'_n \mathbf{M}'_n \mathbf{C}_n \mathbf{M}_n \mathbf{u}_n,
\]

\[
\tau_n = n^{-1} \mathbf{a}'_n \mathbf{C}_n \mathbf{e}_n = n^{-1} \mathbf{u}'_n \mathbf{C}_n \mathbf{u}_n - 2\rho_n n^{-1} \mathbf{u}'_n \mathbf{M}'_n \mathbf{C}_n \mathbf{u}_n + \rho_n n^{-1} \mathbf{u}'_n \mathbf{M}'_n \mathbf{C}_n \mathbf{M}_n \mathbf{u}_n,
\]

where \( \mathbf{C}_n = \text{diag}_{i=1,...,n}(a_{i,n} b_{i,n}) \). Given the maintained assumptions the row and column sums of the respective matrices forming the quadratic forms on the r.h.s. of the above equations are uniformly bounded in absolute value by some constants that depend monotonically on \( c \) as well as other bounds maintained in the assumptions; compare again Remark A.1 in Kelejian and Prucha (2004). It now follows from Remark C.2 after the proof of Lemma C.1, the triangle inequality.
and observing that $\tilde{\rho}_n - \rho_n = o_p(1)$, that there exist random variables $\varsigma_{2,n}$ that do not depend on $a_n$ and $b_n$ as well as a constant $k(c)$ that depends monotonically on $c$ (as well as on some other bounds maintained in the assumptions) such that

$$|\tilde{\tau}_n - \tau_n| = k(c)\varsigma_{2,n} \quad (C.28)$$

and $\varsigma_{2,n} = o_p(1)$.

The first claim of part (a) of the lemma follows immediately form (C.25), (C.26) and (C.28). The second claim is obvious observing that $|n^{-1}a_n\Sigma_n b_n| \leq n^{-1}\sum_{i=1}^n |a_{i,n}| |b_{i,n}| \sigma_{i,n}^2 \leq c^2 c_* < \infty$. Part (b) of the lemma follows form (C.25), (C.27) and (C.28) with $K(c) = c^2 + 2c^2 c_* + k(c)$ and $\varsigma_n = \varsigma_{1,n} + \varsigma_{2,n}$, observing that $\varsigma_{1,n}$ and $\varsigma_{2,n}$ are nonnegative.

**Lemma C.6**: Suppose Assumptions 1 - 4 hold. Furthermore assume that $\sup_n |\rho_n| < 1$, and the row sums and column sums of $M_n$ are bounded uniformly in absolute value by, respectively, one and some finite constant. Let $\varepsilon_n = (I_n - \rho_n M_n)u_n$, and let $\tilde{\varepsilon}_n = (I_n - \tilde{\rho}_n M_n)u_n$ with $u_n = u_n + D_n \Delta_n$ and $D_n = [d_{1,n}, \ldots, d_{n,n}]'$, where $\tilde{\rho}_n$ can be any estimator that satisfies $\tilde{\rho}_n - \rho_n = o_p(1)$. Let

$$F_n = \bar{F}_n = H_n$$

or

$$F_n = (I_n - \rho_n M_n)^{-1} H_n \quad \text{and} \quad \bar{F}_n = (I_n - \tilde{\rho}_n M_n)^+ H_n,$$

where $H_n$ is an $n \times p_*$ matrix whose elements are uniformly bounded in absolute value, let $\Sigma_n = \diag_{i=1,\ldots,n}(\sigma_i^2)$ and $\tilde{\Sigma}_n = \diag_{i=1,\ldots,n}(\tilde{\sigma}_i^2)$, then $n^{-1}F_n' \tilde{\Sigma}_n F_n - n^{-1}F_n' \Sigma_n F_n = o_p(1)$ and $n^{-1}F_n' \Sigma_n F_n = O(1)$.\footnote{We would like to thank Benedikt Pötscher for very helpful comments on parts of the proof of this lemma.}

**Proof.** The proof will focus on the case where $F_n = (I_n - \rho_n M_n)^{-1} H_n$ and $\bar{F}_n = (I_n - \tilde{\rho}_n M_n)^+ H_n$ in that it will be obvious that the arguments implicitly also cover the case where $F_n = \bar{F}_n = H_n$.

Clearly under the maintained assumptions there exists a $\rho_*$ with $\sup_n |\rho_n| \leq \rho_* < 1$ and so the row sums and column sums of $\rho_* M_n$ are bounded uniformly in absolute value by, respectively, one and some finite constant.

Now let $\nu_{r,s}$ denote the difference in the $(r,s)$-th elements of $n^{-1}F_n' \tilde{\Sigma}_n F_n$ and $n^{-1}F_n' \Sigma_n F_n$. Then

$$\nu_{r,s} = \sum_{i=1}^7 \nu_{i,r,s} \quad (C.29)$$

\[\text{Proof.}\]
where

\[ \nu_{1,n} = \frac{1}{n} (\tilde{\mathbf{f}}_{r,n} - \mathbf{f}_{r,n})' (\mathbf{\Sigma}_n - \mathbf{\Sigma}) (\tilde{\mathbf{f}}_{s,n} - \mathbf{f}_{s,n}) \] (C.30)

\[ \nu_{2,n} = \frac{1}{n} (\tilde{\mathbf{f}}_{r,n} - \mathbf{f}_{r,n})' (\mathbf{\Sigma}_n - \mathbf{\Sigma}) \mathbf{f}_{s,n} \]

\[ \nu_{3,n} = \frac{1}{n} (\tilde{\mathbf{f}}_{r,n}'(\mathbf{\Sigma}_n - \mathbf{\Sigma}) (\tilde{\mathbf{f}}_{s,n} - \mathbf{f}_{s,n}) \]

\[ \nu_{4,n} = \frac{1}{n} (\tilde{\mathbf{f}}_{r,n}'(\mathbf{\Sigma}_n - \mathbf{\Sigma}) \mathbf{f}_{s,n} \]

\[ \nu_{5,n} = \frac{1}{n} (\tilde{\mathbf{f}}_{r,n} - \mathbf{f}_{r,n})' (\mathbf{\Sigma}_n \mathbf{f}_{s,n} \]

\[ \nu_{6,n} = \frac{1}{n} (\tilde{\mathbf{f}}_{r,n} - \mathbf{f}_{r,n})' \mathbf{\Sigma}_n \mathbf{f}_{s,n} \]

\[ \nu_{7,n} = \frac{1}{n} (\tilde{\mathbf{f}}_{r,n}'(\mathbf{\Sigma}_n) (\tilde{\mathbf{f}}_{s,n} - \mathbf{f}_{s,n}) \]

and

\[ \tilde{\mathbf{f}}_{s,n} - \mathbf{f}_{s,n} = \left[ (\mathbf{I}_n - \bar{\rho}_n \mathbf{M}_n)^+ - (\mathbf{I}_n - \rho_n \mathbf{M}_n)^{-1} \right] \mathbf{h}_{s,n}. \]

In the following we will be confronted with terms of the form

\[ \chi_n^{(k,l)} = \frac{1}{n} \rho_n^{l+k} \mathbf{h}_{r,n}' \mathbf{M}_n^k \mathbf{h}_{s,n} - \frac{1}{n} \rho_n^{l+k} \mathbf{h}_{r,n}' \mathbf{M}_n^k \mathbf{h}_{s,n}. \] (C.31)

Under the maintained assumptions the row sums of \( \rho_n^k \mathbf{M}_n^k \) are bounded uniformly in absolute value by one; this is readily seen by arguments like those in Kelejian and Prucha (1999, p. 526). Let \( c < \infty \) be a bound for the absolute elements of \( \mathbf{H}_n \), then it follows that \( c \) is also a bound for the absolute elements of \( \rho_n^k \mathbf{M}_n^k \mathbf{h}_{s,n} \). Given this it follows immediately form Lemma C.5 that \( \chi_n^{(k,l)} = o_p(1) \) and that there exists a random variable \( \varsigma_n = o_p(1) \) and a constant \( K(c) \) such that

\[ \left| \chi_n^{(k,l)} \right| \leq K(c)(1 + \varsigma_n). \] (C.32)

In the following let \( c \) be such that also \( \sigma^2_{\epsilon,n} \leq c \).

In proving the lemma we will use the usual subsequence argument that utilizes that a sequence of random vectors taking their values in \( \mathbb{R}^k \), \( 1 \leq k \leq \infty \), converges in probability if for every subsequence there exists a subsequence such that the random vectors converge almost surely; see, e.g., Gänsler and Stute (1977), pp. 61-62 and p. 332. Also observe that convergence in probability [almost sure convergence] of random vectors taking their values in \( \mathbb{R}^k \), \( 1 \leq k \leq \infty \), is equivalent with convergence in probability [almost sure convergence] for each of the coordinates of the random vector. Now let \( (n_m) \) denote some subsequence, then there exists a subsequence \( (n'_m) \) such that for \( \omega \in A, P(A) = 1 \),

\[ \left| \bar{\rho}_{n'_m} (\omega) - \rho_{n'_m} \right| \to 0, \quad \varsigma_{n'_m} (\omega) \to 0, \quad \chi_{n'_m}^{(k,l)} (\omega) \to 0, \quad \varsigma_{n'_m} (\omega) \leq K(c) \] and \( \left| \bar{\rho}_{n'_m} (\omega) \right| \leq \rho_{**} \),

as \( n_m \to \infty \). Consequently there exists an index \( N_\omega \) such that for all \( n'_m \geq N_\omega \):

\[ \varsigma_{n'_m} (\omega) \leq K(c) \] and \( \left| \bar{\rho}_{n'_m} (\omega) \right| \leq \rho_{**} \),

(C.34)
where $\rho_{ss} = (\sup n |\rho_n| + \rho_*)/2$.

In the following assume that $n'_m \geq N_\omega$. Since $|\tilde{\rho}_n'(\omega)| < \rho_*$ the row sums of $\tilde{\rho}_n'(\omega)M_{n'}$ are less than unity in absolute value. In light of Horn and Johnson (1985), p. 301, it then follows that $I_{n'_m} - \tilde{\rho}_n'(\omega)M_{n'_m}$ is invertible and that

$$\left( I_{n'_m} - \tilde{\rho}_n'(\omega)M_{n'_m} \right)^+ = \left( I_{n'_m} - \rho_{n'_m}M_{n'_m} \right)^{-1} = \sum_{l=1}^{\infty} \left[ \tilde{\rho}_n'(\omega) - \rho_{n'_m} \right] M_{n'_m}^l.$$

Hence in light of the definition of $\nu_{1,n}$ in (C.30) we have

$$\nu_{1,n}(\omega) = \sum_{l=1}^{\infty} \sum_{k=1}^{\infty} \chi^{(k,l)}_{n'_m}(\omega)$$

with

$$\chi^{(k,l)}_{n'_m}(\omega) = \left( \tilde{\rho}_n'(\omega) - \rho_{n'_m} \right) / \rho_*^l \left( \tilde{\rho}_n'(\omega) - \rho_{n'_m} \right) / \rho_*^k \chi^{(k,l)}_{n'_m}(\omega).$$

Clearly $\chi^{(k,l)}_{n'_m}(\omega) \to 0$ in light of (C.33) and (C.34). Furthermore, observing that

$$\left| \tilde{\rho}_n'(\omega) - \rho_{n'_m} \right| / \rho_*^l \leq 2(\rho_{ss}/\rho_*)^l$$

and $\left| \chi^{(k,l)}_{n'_m}(\omega) \right| \leq 2K(c)$ we have $\chi^{(k,l)}_{n'_m}(\omega) \leq B^{(l,k)}$ with $B^{(l,k)} = 8K(c)(\rho_{ss}/\rho_*)^l$. Since $\rho_{ss}/\rho_* < 1$ by construction clearly

$$\sum_{l=1}^{\infty} \sum_{k=1}^{\infty} B^{(l,k)} < \infty.$$ Hence it follows from dominated convergence that $\nu_{1,n}(\omega) \to 0$ as $n_{n'_m} \to \infty$. This completes the proof that $\nu_{1,n} = o_p(1)$.

By analogous arguments we also see that $\nu_{i,n} = o_p(1)$ for $i = 2, \ldots, 7$. Hence $\nu_n = o_p(1)$ and thus $n^{-1} \tilde{F}' \tilde{\Sigma} \tilde{F}_n - n^{-1} \tilde{F}' \tilde{\Sigma} \tilde{F}_n = o_p(1)$. That $n^{-1} \tilde{F}' \tilde{\Sigma} \tilde{F}_n = O(1)$ follows from the properties maintained for the row and column sums of $(I_n - \rho_n M_n)^{-1}$ and the elements of $\Sigma_n$ and $H_n$. ■

**Proof of Theorem 3:** We first demonstrate that $\tilde{\Psi}_n - \Psi_n = o_p(1)$, utilizing the expressions for the elements of $\tilde{\Psi}_n$ and $\Psi_n$ in (C.15) and (C.16). Observe that under the maintained assumption the row and column sums of the absolute elements of the matrices $A_{r,n}$ and $A_{s,n}$ are uniformly bounded, and thus clearly are those of the matrices $A_n = (a_{ij,n})$ with $a_{ij,n} = (a_{ij,r,n} + a_{ij,s,n} + a_{ij,s,n})$. It then follows directly from Lemmata C.3 and C.4 that $\psi_{rs,n} = o_p(1)$.

$$\psi_{rs,n} = O(1) \text{ and } \tilde{\psi}_{rs,n} = O_p(1).$$

Observing that the row and column sums of $(I_n - \rho_n M_n) (A_{r,n} + A_{r,n}^*) (I_n - \rho_n M_n)$ are bounded uniformly in absolute value it follows from Lemma C.1 that $\tilde{\alpha}_{r,n} = \alpha_{r,n} = o_p(1)$ and hence $\tilde{\alpha}_{r,n} = O_p(1)$. By assumption $\tilde{P}_n = P_n$ is $o_p(1)$, and hence $P_n = O_p(1)$. Observe that by Lemma C.6 we have $n^{-1} \tilde{F}' \tilde{\Sigma} \tilde{F}_n = n^{-1} \tilde{F}' \tilde{\Sigma} \tilde{F}_n = o_p(1)$, and hence $n^{-1} \tilde{F}' \tilde{\Sigma} \tilde{F}_n = O(1)$. Thus $\psi_{rs,n} = o_p(1)$, $\psi_{rs,n} = O(1)$, and hence $\tilde{\psi}_{rs,n} = o_p(1)$ and $\tilde{\psi}_{rs,n} = O(1)$.

By Assumption 5 we have $\tilde{T}_n - T_n = o_p(1)$, and thus $T_n = O_p(1)$. Let $\tilde{\Xi}_n = \tilde{J}_n T_n J_n$ and $\tilde{\Xi}_n = \tilde{J}_n T_n J_n$, then, as demonstrated in the proof of
Theorem 2, \( \tilde{J}_n = O_p(1) \), \( J_n = O(1) \), \( \tilde{\Xi}_n^+ = O_p(1) \) and \( \Xi_n^{-1} = O_p(1) \), and furthermore \( J_n - \tilde{J}_n \xrightarrow{p} 0 \) and \( \tilde{\Xi}_n^+ - \Xi_n^{-1} \xrightarrow{p} 0 \) as \( n \to \infty \). (There is a slight difference in the definition of \( \tilde{\Xi}_n \) here and in the proof of Theorem 2, which does not affect the claim.) Given the above results it is now obvious that \( \Omega_{\tilde{p}_n} - \Omega_{p_n} = o_p(1) \).

**Proof of Theorem 4:** We concentrate again on the case \( F_n = (I_n - \rho_n M_n)^{-1} H_n \). The first line in (27) is seen to hold in light of Assumption 7 and Theorem 2. We next verify that \( \xi_{o,n} \xrightarrow{d} N(0, I_{p,n+2}) \) utilizing the central limit theorem for vectors of linear quadratic forms given above as Theorem A.1. By assumption \( \lambda_{\min}(\Psi_{o,n}) \geq c_{\Psi_{o,n}} > 0 \). In proving Theorem 2 we verified that the innovations \( \varepsilon_n \) and the elements of \( A_{r,n} \) and \( J_{r,n} \) appearing in \( v_n \) all satisfy the conditions of the central limit theorem. Since the row and column sums of \( (I_n - \rho_n M_n)^{-1} \) and the elements of \( H_n \) are uniformly bounded in absolute value it follows that the elements of \( F_n \) are also uniformly bounded in absolute value. Thus all conditions of Theorem A.1 are satisfied, which verifies the claim.

In proving Theorems 2 and 3 we have shown that \( \Psi_n - \Psi_{o,n} = o_p(1), \Psi_n = O(1) \) and thus \( \Psi_{n} = O_p(1) \). By analogous argumentation it is readily seen that the other sub-matrices of \( \Psi_{o,n} \) and \( \Psi_{o,n} \) have the same properties, and thus \( \Psi_{o,n} - \Psi_{o,n} = o_p(1) \) and \( \Psi_{o,n} = O(1) \). By assumption \( \tilde{P}_n - P_n = o_p(1), P_n = O(1) \) and thus \( \tilde{P}_n = O_p(1) \), and furthermore \( \tilde{\gamma}_n - \gamma_n = o_p(1), \gamma_n = O(1) \) and thus \( \tilde{\gamma}_n = O_p(1) \). In proving Theorem 2 we have verified that \( \tilde{J}_n - J_n \xrightarrow{p} 0, J_n = O(1) \) and \( J_n = O_p(1) \), and furthermore that \( (J'_n \tilde{\gamma}_n J_n)^{+} - (J'_n \gamma_n J_n)^{-1} = o_p(1), (J'_n \tilde{\gamma}_n J_n)^{+} = O_p(1) \) and \( (J'_n \gamma_n J_n)^{-1} = O(1) \). The claim that \( \Omega_{o,n} - \Omega_{o,n}(\tilde{\gamma}_n) = o_p(1) \) and \( \Omega_{o,n} = O(1) \) is now obvious.

**D Appendix: Proofs for Section 4**

**Proof of Lemma 3:** Utilizing (3) it follows from Assumptions 3, 8 and \( \sup_n \| \beta_n \| < \infty \) that all columns of \( Z_n = [X_n, W_n Y_n] \) are of the form \( \vartheta_n = \pi_n + \Pi_n \varepsilon_n \), where the elements of the \( n \times 1 \) vector \( \pi_n \) are bounded in absolute value and the row and column sums of the \( n \times n \) matrix \( \Pi_n \) are uniformly bounded in absolute value by some finite constant; compare, e.g., Remark A.1. in Kelejian and Prucha (2004). The claims that the fourth moments of \( D_n = -Z_n \) are uniformly bounded by a finite constant, and that Assumption 6 holds, now follows directly from Lemma C.2.

Clearly

\[ n^{1/2}(\tilde{\delta}_n - \delta_n) = \tilde{P}_n^{1/2} \Psi_n \tilde{F}_n \varepsilon_n \]

where \( \tilde{P}_n \) is defined in the lemma and \( \tilde{F}_n = (I_n - \rho_n M_n)^{-1} H_n \). Given Assumption 10 clearly \( \tilde{P}_n = P_n + o_p(1) \) and \( P_n = O(1) \), with \( P_n \) defined in the lemma. Since by Assumption 3 the row and column sums of \( (I_n - \rho_n M_n)^{-1} \) are uniformly
bounded in absolute value, and since by Assumption 9 the elements of $H_n$ are uniformly bounded in absolute value, it follows that the elements of $F_n$ are uniformly bounded in absolute value. By Assumption 2, $E(\varepsilon_n) = 0$ and its diagonal VC matrix, $\Sigma_n$, has uniformly bounded elements. Therefore, $\lim_{n \to \infty} F_n' \varepsilon_n = 0$ and the elements of $VC(n^{-1/2}F_n' \varepsilon_n) = n^{-1}F_n' \Sigma_n F_n$ are also uniformly bounded in absolute value. Thus, by Chebyshev’s inequality $n^{-1/2}F_n' \varepsilon_n = O_p(1)$, and consequently $n^{1/2}(\delta_n - \delta_n) = P_n n^{-1/2} F_n' \varepsilon_n = O_p(1)$ and $P_n n^{-1/2} F_n' \varepsilon_n = O_p(1)$. This completes the proof recalling that $T_n = F_n^* P_n$.

**Proof of Lemma 4:** Note from (1) and (2) that

$$y_n^*(\hat{\rho}_n) = Z_n^*(\hat{\rho}_n) \delta_n + \varepsilon_n - (\hat{\rho}_n - \rho_n) M_n u_n$$

and hence

$$n^{1/2}[\delta_n(\hat{\rho}_n) - \delta_n] = \left[n^{-1/2} \hat{Z}_n^*(\hat{\rho}_n) Z_n^*(\hat{\rho}_n)\right]^{-1} n^{-1/2} \hat{Z}_n^*(\hat{\rho}_n) [\varepsilon_n - (\hat{\rho}_n - \rho_n) M_n u_n]$$

$$= P_n^* [n^{-1/2} F_n^* \varepsilon_n - (\hat{\rho}_n - \rho_n) n^{-1/2} F_n^* \varepsilon_n],$$

where $P_n^*$ is defined in the lemma, and with $F_n^* = H_n$ and $F_n^{**} = (I_n - \rho_n M_n)^{-1} M_n H_n$. In light of Assumption 10, and since $\hat{\rho}_n$ is $n^{1/2}$-consistent, it follows that

$$n^{-1} \hat{Z}_n^*(\hat{\rho}_n) Z_n^*(\hat{\rho}_n) - Q_{HZn}^*(\rho_n) Q_{HHn}^{-1} Q_{Hzn}^*(\rho_n) = o_p(1).$$

Since by Assumption 10 we have $Q_{HZn}^*(\rho_n) Q_{HHn} Q_{Hzn}^*(\rho_n) = O(1)$ and $[Q_{HZn}^*(\rho_n) Q_{HHn} Q_{Hzn}^*(\rho_n)]^{-1} = O(1)$ it follows that

$$[n^{-1} \hat{Z}_n^*(\hat{\rho}_n) Z_n^*(\hat{\rho}_n)]^{-1} - [Q_{HZn}^*(\rho_n) Q_{HHn}^{-1} Q_{Hzn}^*(\rho_n)]^{-1} = o_p(1);$$

compare, e.g., Pötscher and Prucha (1997), Lemma F1. In light of this it follows further that $P_n^* - P^*_n = o_p(1)$ and $P_n^* = O(1)$, with $P_n^*$ defined in the lemma. By argumentation analogous to that in the proof of Lemma 3 it is readily seen that $n^{-1/2} F_n' \varepsilon_n = O_p(1)$ and $n^{-1/2} F_n' \varepsilon_n = O_p(1)$. Consequently $n^{1/2}[\delta_n(\hat{\rho}_n) - \delta_n] = P_n^* n^{-1/2} F_n' \varepsilon_n + o_p(1)$ and $P_n^* n^{-1/2} F_n' \varepsilon_n = O_p(1)$, observing again that $\hat{\rho}_n - \rho_n = o_p(1)$. This completes the proof recalling that $T_n^* = F_n^* P_n^*$. ■
