Abstract

Employees' wellbeing is important to the firms. Analysis of job satisfaction may give insight into various aspect of labor market behavior, such as worker productivity, absenteeism and job turn over. Little empirical work has been done on the relationship between structure of working environment and job satisfaction. This paper investigates the relationship between working environment, firm size and worker job satisfaction. We use a unique data of 28,240 British employees, Workplace Employee Relations Survey. In this data set the employee questionnaire is matched with the employer questionnaire. Four measures of job satisfaction considered are satisfaction with influence over job, satisfaction with amount of pay, satisfaction with sense of achievement and satisfaction with respect from supervisors. They are all negatively related to the firm size implying lower levels of job satisfaction in larger firms. The firm size in return is negatively related to the degree of flexibility in the working environment. The small firms have more flexible work environments. We further find that, contrary to the previous results lower levels of job satisfaction in larger firms can not necessarily be attributed to the inflexibility in their structure of working environment.

Key Words: Job Satisfaction, Firm Size, Working Environment, Linked Employer-Employee data, Britain.

JEL Classifications: J21, J28, J29, J81

1. Introduction

Working environment refers to the place and the conditions under which one works. Workers that are comfortable within their working environment will be happier, work more efficiently, with greater ease and feel engaged than those who are uncomfortable in their working environment. Unfavorable working environment may contribute to stress and health problems. This can affect the job satisfaction of the employees, their productivity, absenteeism, lateness, quit behavior, job turnover, loyalty and commitment to the firms, innovation and creativity. These in turn affect the firm's productivity and profitability. For this reason, the structure of work environment is important. This paper investigates the job satisfaction in relation to the structure of work environment and the firm size. Understanding the structure of working environment and job satisfaction has important economic implications. Exploration of these issues is the aim and one of the contributions of this paper.

To the best of our knowledge there are only two studies on the topic of job satisfaction, firm size and structure of working environment. The earliest study is by Idson (1990) for the USA. The second study is by Garcia-Serrano (2011) for Spain. Our contribution to the empirical literature on the interrelationships among job satisfaction, firm size and working environment is as follows. We use a unique data set from Britain and provide evidence from Britain. The data set comes from Workplace Employee Relations Survey (WERS) (1998). This unique data includes a set of questions on the structure of work conditions. They are as follows. Workers have some or a lot of influence on the range of tasks they do in their job; on the pace at which they work and how they do their work. It also includes information on availability of flexible working hours, job sharing, parental leave and working from home, there are four indicators of job satisfaction available in this data set that cover different aspects of workers' job satisfaction. They are satisfaction with influence over job, satisfaction with amount of pay, satisfaction with sense of achievement and satisfaction with respect from supervisors. Satisfaction with pay is the most often studied indicator in the literature. The other three indicators of job satisfaction we use in this paper are not studied as often. The three main questions asked in this paper are as follows. How does structure of working environment vary by the firm size? Namely which aspects of the structure of work environment are

important in large or small firms? How does job satisfaction vary by firm size? Finally, what role does structure of working environment play in explaining the effect of firm size on job satisfaction?

Our main findings can be summarized as follows. First, the structure of work environment is more regimented in larger firms than in smaller firms when considering the influence that the workers have over the pace of their work, over what they do and how they do it. We consistently find that the firm size is negatively related to the latter attributes of the work conditions. Second, the job satisfaction is lower in larger firms than in smaller firms as it is often reported in the literature. Third, the regimentation in large firms do not play a significant a role in explaining the lower levels of job satisfaction in larger firms contrary to the findings of Idson (1990) with the USA data and the findings of Garcia-Serrano (2011) with the Spanish data. There may be other factors contributing to lower levels of job satisfaction in larger firms. Such as poor management-employee relations (Tansel and Gazioglu, 2014) and other factors. These results have important policy implications for the employees and the firms. Improving regimentation in the structure of working environment in large firms could be important. In fact, one of our findings suggest that large firms are attempting to make up for the regimentation in their work environment by providing alternative work amenities such as flexible working hours, job sharing, parental leave and working from home. Such amenities are found to be better provided in large firms than in small ones.

We organize the paper in the following manner. In Section 2 we provide a brief review of literature. Section 3 introduces the data and the variables used in empirical analysis. The firm size and the structure of working environment is investigated in Section 4. In Section 5 job satisfaction is related to the firm size and structure of work environment. Concluding remarks are presented in Section 6.

2. Brief Review of Literature

The literature on Job satisfaction has expanded enormously recently and attracted attention of researchers from a variety of social science disciplines such as sociology, psychology, anthropology, management sciences and labor economics. The relationship of job satisfaction to worker behavior such as productivity, job performance, motivation, quit, job turnover, lateness and

absenteeism in the workplace are emphasized by a number of authors. These in turn affect the productivity and the profits of the firms. Iaffaldano and Muchinsky (1985) consider job satisfaction, productivity and job performance. Böckerman and Ilmakunnas (2012) find a positive relationship between job satisfaction and firm level productivity in Finnish manufacturing plants. Akerlof, Rose and Yellen (1988) and Clark et al. (1998) and more recently Kristensen and Westgard-Nielsen (2004) and Levy-Garboua et al. (2007) indicate that job satisfaction is as good a predictor of quits and absenteeism as wages are. They point out that individuals leave low-satisfaction jobs for high-satisfaction jobs. Thus, job satisfaction gives useful information about job turnover also. For these reasons it is important to study the various aspects of job satisfaction. Most of the studies on job satisfaction are concentrated on Britain or the USA. Recently there is evidence from other countries as well. Linz (2003) in Russia, Hinks (2010) in South Africa and Drydakis (2012) in Greece and other studies investigated various aspects of job satisfaction.

Gazioglu and Tansel (2006) and Clark (1996) used British data from WERS and BHPP sources respectively and investigated job satisfaction with various individual and firm characteristics. Danzer (2013) in Ukraine, Demoussis and Giannakopoulos (2007) in Greece, Ghinetti (2007) in Italy, Luechinger, Stutzer and Winkelmann (2010), Taylor and Westover (2011) and Wright and Davis (2013) explored job satisfaction in public and private employment. Recently Danzer (2019) find in Ukraine higher public sector job satisfaction and negative selection of individuals into the public sector. Asiedu and Folmer (2007) find a positive relationship between privatization and job satisfaction. Donohue, S. and J. Heywood, (2004), Clark and Oswald (1996), Mumford and Smith (2012) and Card et al. (2012) investigated dependence of job satisfaction on relative wage. McCausland, Pouliakas and Theodossiou (2005), Artz (2008) and Green and Heywood (2008) studied the performance pay and job satisfaction. Javdani and Krauth (2020) find in Canada that the co-worker pay has a positive effect on both pay and job satisfaction however the effect on job satisfaction disappears when firm level fixed effects are used.

Bryson, Cappellari and Lucifora (2010) find that job satisfaction and union membership are negatively associated but, the effect disappears when selection into membership is taken into account. Blanchflower and Bryson (2020) find a positive relationship between union membership and worker job satisfaction contrary to the previous works using data from United States and

Europe. Kawata and Owan (2020) investigate the positive and negative peer effects of elderly groups on young group's productivity or motivation in a Japanize firm.

It is a well-established result in the literature that women are more satisfied than men controlling for job, family and personal attributes (Clark, 1997). However, a recent study by Redmond and McGuinness (2019) using data from European countries find that the gap between job satisfaction of men and women disappear when job preferences are taken into account since work-life balance is important for women. Educational mismatch and job satisfaction has been a popular topic to study. Many studies indicate that over-qualified workers are less satisfied. For this reason, firms try to hire adequately qualified workers. Peiro, Agut and Grau. (2010) among young Spanish workers and Verhaest and Verhofstadt (2016) among young Flemish workers in Belgium find lower job satisfaction among the overqualified. However, Garcia-Mainar and Montuenga-Gomez (2020) find that in Spain over-qualified are less satisfied but opposite is true when endogeneity is taken into account.

Clark (2011) in a study of the job satisfaction and the state of the macro economy in Britain finds that worker's mental well-being, pay satisfaction and job security satisfaction are higher in booms but, satisfaction with the work itself and overall job satisfaction are higher in busts Pilipiec, Groot and Pavlova (2020) find that workers in Netherlands were more satisfied with their job during the recession of 2008-2013 and job satisfaction decreased after the recession e

Recent availability of surveys including questions on job satisfaction enabled studies on job satisfaction and its various aspects in developing countries also. Some of the studies from developing countries are as follows. McKay, Newell and Rienzo (2018) find in Madagascar, Malawi, Uganda, and Zambia, being over-educated or under-educated in the current job negatively influences job satisfaction. Berker (2015) investigated the effect of informal employment on job satisfaction in Turkey. Zeqiri and Aziri (2010) explored the role of gender and education in job satisfaction in Macedonia.

Studies on the structure of work environment goes back to as early as 1960s. Scherer (1976) examined the structure of work at different firm sizes and job satisfaction. Using 1973 Quality of

Employment Survey (QES), he found that job satisfaction was lower in large firms. Same result was reported by Stafford (1980), Kwoka (1980), Idson (1990), and Dunn (1980; 1986). Clark (1996) also reported lower job satisfaction in larger firms in Britain but, a recent study by Marlow, Patton and Ram (2004) rejects the negative relationship between job satisfaction and the firm size.

Analysis of the impact of work environment on job satisfaction and structure of work by firm size has taken less attention in the previous studies. Idson (1990) used USA data from Quality of Life Survey (1977) and Garcia-Serrano (2011) used Spanish data from Working Conditions Survey (2001 to 2004) in order to examine the interrelationship among the work environment, firm size and job satisfaction and they both reached similar conclusions. They found that higher regimentation in the work environment of the larger firms leads to lower levels of job satisfaction. Stafford (1980) and Oi (1983) developed models with the outcome of greater rigidity¹ in the work structure of larger firms. However, the previous studies did not investigate these interrelationships empirically except Idson and Garcia-Serrano. The present study considers this case with data from Britain.

3. The Data and Variables

We use the data from the 1998 Workplace Employee Relations Survey (WERS), of the Department of Trade and Industry in Britain. It is linked employer-employee data. It is a nationally representative survey including 28,240 employees in over 3000 firms. The three-quarters of all employees in Britain (about 15.8 million workers) are covered. The interviews are conducted with employees and managers face to face with the most senior manager. It covers all sectors of the economy except agriculture. This unique data is rich in individual characteristics and workplace characteristics including working conditions and job satisfaction.

¹ Optimal amount of job search is lower for workers in large firms due to higher mobility costs in large firms (Oi, 1983). Oi developed a model that endogenously generates a more regimented working environment in larger firms. He suggested that in the larger firms structure of work environment is more regimented, since large firms endeavor to minimize the opportunity cost of the high ability managers that they attract. Another argument proposed to explain greater regimentation in large firms is as follows. Larger firms are capital intensive and require its continuous use. This will constrain workers in the ways they perform their tasks. Therefore, this will generate greater regimentation in the structure of working environment (Garcia- Serrano, 2011).

The working condition variables use are as follows. Workers have some or a lot of influence on the range of tasks they do in their job; on the pace at which they work and how they do their work. We also include the information on availability of flexible working hours, job sharing, parental leave and working from home, we treat these two groups of working conditions separately while we explore the relationship between structure of work environment and firm size.

WERS includes important information related to workers' job satisfaction. An overall job satisfaction was not asked. But, workers were questioned with four different aspects of their job. They are satisfaction with influence over job, with amount of pay, with sense of achievement and with respect from supervisors. Each of them are recorded as five point Likert scale. One corresponds to "very dissatisfied", two to "dissatisfied", three to "neither satisfied nor dissatisfied", four to "satisfied" and five to "very satisfied". The distributions of the four job satisfaction indicators are given in Table 1. The most common response (mode) is the "satisfied" category in all indicators except for the satisfaction with pay indicator where nearly 41 percent of the employees are either "dissatisfied" or "very dissatisfied". At the top tail of the distribution, those who are "very satisfied" with their pay are only 3.5 percent while this is about 11-15 percent for all other indicators of job satisfaction. Thus, we can confidently say that British workers are less satisfied with their pay but are more satisfied with their influence over their job, with their sense of achievement and with respect they receive from their supervisors.

[Table 1 about here]

Firm size is measured by the number of the workers at the firm. Table 2 shows the means for the four job satisfaction indicators by five different categories of the firm size. We observe in this table that percentages of those who are "satisfied" or "very satisfied" with their influence over their job, with their sense of achievement and with respect they receive from their supervisor's decrease continuously as the firm size increases from 10-25 to 500 or more workers. Notice that, the proportion of those who are very satisfied with their influence over their job decreases from 14 percent to 10 percent as the firm size increases. Similarly, for the other indicators of job satisfaction except with the satisfaction with pay where the proportion of those who are satisfied or very satisfied with pay stays around the same as the firm size increases. To conclude, we can say that employees are less satisfied in large firms. We also observe that job satisfaction measures indicate

a nonlinear relationship to the firm size. Therefore, while investigating the effect of the firm size in relation to the structure of working environment and in relation to job satisfaction we introduce the natural logarithm of the firm size in all estimations in order to consider the relevant nonlinearities.

[Table 2 about here]

In the rest of the estimations in this study the control variables used are as follows. The variables which are continuous are indicated as so in the parenthesis. The rest of the variables are dummy variables taking values of one for the indicated variable and zero otherwise. Male, Age (continuous), Education, health problems, Race, Log Weekly Income (continuous), Log Hours of Work (continuous) Union Member, Occupation Variables, Gender Concentration, Industrial Composition and Training.

In Section 4 we present and discuss our first set of equations provided in Tables 3 and 4. In these tables various indicators of structure of work environment (which are the dependent variables) are related to the firm size and a rich set of control variables. These equations are probit equations and estimated by maximum likelihood method. In Section 5 the second set of equations estimated are presented in Tables 5 and 6 and discussed. In these tables four indicators of job satisfaction (which are the dependent variables with five ordered categories) are related to firm size and a rich set of control variables. These equations are ordered probit equations and are estimated by maximum likelihood method. The equations in Table 5 do not include the variables on structure of work environment. The equations in Table 6 include structure of working environment variables as further explanatory variables. We compare the coefficient estimates of the of the firm size in the Tables 5 and 6 in order to observe the effect of working environment on job satisfaction.

4. Firm Size and the Structure of Work Environment

A number of researchers postulated that structure of working environment is more rigid in larger firms than in smaller ones. In this section we test this hypothesis. Rigidity in the structure of work environment has implications for worker satisfaction. In this section we estimate maximum likelihood probit regressions that relate various measures of working environment to the firm size.

Tables 3 and 4 report our estimation results, using various measures of the structure of work environment. In these tables, the dependent variables are binary variables about the structure of work environment. The probit regressions also include a rich set of control variables.

4.1 Firm Size and Structure of Working Environment

Firm Size in relation to the job satisfaction is widely studied (Kwoka, (1980) and others). However, studies on firm size in relation to working environment are scanty (Idson, 1990; Garcia-Serrano, 2011). This is the focus of this section. Table 3 reports the probit estimation results when the dependent variables are binary and indicate various measures about the structure of working environment. For instance, if workers have some or a lot of influence about the range of tasks they do in their work then the dependent variable takes the value of one and zero otherwise. Similarly, the other dependent variables in this table are binary variables. The results confirm the conclusion reached by Idson (1990) with the USA data and Garcia-Serrano (2011) with the Spanish data. We consistently find that the firm size is negatively related to the amount of influence the workers have over the range of tasks they do, over the pace at which they work and over how they do their work. In large establishments the workers have less influence over the range of tasks they do, over the pace at which they work and over how they do their work. Thus, in the large firms, employees face greater rigidity in the organization of work than in the smaller firms. We now briefly comment on some of the other covariates reported in Table 3. First of all, both genders are equally likely to have some or a lot of influence on the range of tasks they do in their jobs and on how they do their job but men are less likely to have some or a lot of influence about the pace at which they work. Similar results hold as workers get senior. It is of interest to note that employees with health problems have consistently less influence over what they do and how they do their job. With regards to education we observe that the “degree and post graduate and A level and O level holders” are all less likely to have some or a lot of influence over the range of their tasks, the pace at which they work and how they work.

[Table 3 about here]

4.2 Firm Size and the Availability of Alternative Work Arrangements

Table 4 reports on another aspect of the structure of working environment. The questions asked in this table are different in nature than the ones in Table 3. However, we are still trying to get a feeling about the structure of working environment in an establishment. Table 4 reports on the following question. If needed would flexible working hours, job sharing, parental leave or working from home be available at your work? This table provides maximum likelihood probit estimation results in relation to the flexibility of hours, days and the place of work which are binary, dependent variables. For instance, if workers could have flexible working hours when needed, then the dependent variable takes a value of one and zero otherwise. Similarly, if job sharing, parental leave or working from home are available when needed then the dependent variable takes the value of one and zero otherwise.

Our main interest is the coefficient estimates of the firm size. variable. These estimates show a positive relationship to the working conditions all cases except in the case of flexible working hours. Interestingly, as the firm size increases the flexible working hours are less likely to be available, implying more rigidity in the organization of work (Albertsen et al., 2008). Whereas job sharing, parental leave and working from home could be considered as characteristics of the large firms and are available routinely in the larger firms. Contemplating the aspects of the working environment, the larger firms could be considered more flexible. It seems they are trying to make up for their regimented working environment considered in the previous section by providing job sharing, parental leave, and working from home.

Regarding the some of the other covariates, we observe the following. Men are more likely to have flexible working hours but less likely to have job sharing, parental leave or working from home. Senior workers are less likely to have flexible working hours or job sharing but, more likely to have parental leave or working from home. Considering education of workers, we observe that “degree and post graduate and Alevel-O level holders are less likely to have flexible hours but, more likely to have job sharing, parental leave or working from home.

[Table 4 about here]

5. Job Satisfaction and Structure of Working Environment

In this section we examine the effect of the structure of working environment on the job satisfaction. Table 2 which is discussed in Section 2 reports the variable means for the four job satisfaction measures we consider and the firm size. We observe from this table that workers in firms with 10-25 employees are more satisfied than the workers in the larger firms. Table 5 reports the estimates of the basic job satisfaction equations which are to be compared with those in Table 6. Table 6 provides the estimates of job satisfaction equations which are expanded by including the structure of working environment variables among the explanatory variables. The job satisfaction equations in Tables 5 and 6 are ordered probit regressions estimated with maximum likelihood technique. The ordered probit regressions are also controlled for with a rich set of worker characteristics and job characteristics variables. Only some of those covariates are reported in Tables 5 and 6.

The Table 5 gives the ordered probit maximum likely estimates of the job satisfaction equations which does not include the structure of working environment variables. We observe that the firm size has a negative and statistically significant coefficient estimates in all four measures of the job satisfaction equations. This implies that job satisfaction is lower in larger firms. This result confirms Clark (1996) and others. Our next aim is to investigate whether the structure of working conditions can account for the lower levels of job satisfaction in larger firms. For this purpose, we compare the estimates of the firm size in Tables 5 and 6. Table 5 gives estimates when structure of working environment variables are not included. Table 6 provides the results when structure of work environment variables are introduced into the ordered probit model. We observe that the coefficient estimates of log firm size in Table 6 are either the same or slightly smaller than those in Table 5 but, still negative and statistically highly significant. Therefore, Table 6 like Table 5 also implies lower levels of job satisfaction in larger firms. Thus, we can say that observed lower levels of job satisfaction in larger firms can not necessarily be attributed to the greater rigidity in the larger firms. This result is contrary to the findings of Idson (1990) with the USA data and Garcia-Serrano (2011) with the Spanish data. They found that the introduction of the work structure variables drove the estimated coefficient on the firm size to zero. This led them to conclude that observed lower levels of worker satisfaction in larger firms may be attributed to the greater rigidity in their working

environment. The difference in our result may be due to impact of differences in cultural values and beliefs among the three countries (Fargher et al. 2008).

[Tables 5 and 6 about here]

In our study, the first set of working structure variables are workers' influence over the range of tasks they do in their job, pace at which they work and how they do their work are observed in Table 6. Their coefficient estimates are all positive and statistically significant in all four measures of job satisfaction. Indicating their availability increases all four measures of job satisfaction. The second set of work environment variables are availability of flexible working hours, job sharing, parental leave and working from home all reported also in Table 6. The coefficient estimates on availability of flexible working hours are statistically significant and have negative effects on all job satisfaction measures. However, the other working environment variables, job sharing, parental leave, and working from home are all statistically insignificant, implying that they do not influence the all four job satisfaction measures. However, there is also evidence that the large firms are making efforts to overcome the regimentation by providing job sharing, parental leave and working from home. A likelihood ratio test of the joint significance of the set of working environment variables (influence over the range of tasks they do in their job, pace at which they work, how they do their work, the availability of flexible work hours, job sharing, parental leave and working from home) indicate that they are jointly statistically significant at the five percent level in all four of the job satisfaction equations implying that they as a group significantly influence the four job satisfaction measures considered. We have also estimated the job satisfaction equations in Table 6 by omitting the second set of work environment variables. Qualitatively the results did not change. As before the coefficient estimates of the firm size were negative and statistically significant in all four job satisfaction equations.

Here we do not discuss the effect of other covariates in the job satisfaction equations which are included as control variables. They are similar to those found elsewhere in the literature. In summary, women are significantly more satisfied with their jobs than men. Job satisfaction decreases with age in a nonlinear fashion. Higher educated are less satisfied than the less educated.

Married are less satisfied than the non-married. Those workers with health problems are less satisfied with all aspects of their jobs. Availability of training increases job satisfaction.

6. Conclusions

In this paper we explored the interrelationship among the firm's structure of working environment, firm size and job satisfaction. We found that in large firms, workers face greater rigidity in the organization of the work than in the smaller firms. We also found consistently negative relationships between firm size and various measures of working environment such as the influence workers have on the range of tasks, the pace of the work and how the work is done. It is of interest to note that those employees with health problems have consistently less influence over what they do and how they do their job. Furthermore, we found that although flexible working hours were less likely to be available in large firms, job sharing, parental leave and working from home were more likely to be available in the large firms.

Flexibility in the structure of work environment contributes to higher levels of job satisfaction. Introducing control measures for the structure of working environment does not drive the effect of firm size on various measures of job satisfaction to zero. This is contrary to the findings of Idson (1990) with USA data and Garcia-Serrano (2011) with Spanish data. They find that lower levels of job satisfaction in larger firms is due to their higher regimented environment. Whereas we found that lower levels of job satisfaction in larger firms is not necessarily due to the higher levels of rigidity in their structure of working environment. There may be other factors responsible for this result such as poor management-employee relations in large firms as discussed by Tansel and Gazioglu (2014) or other factors and differences in cultural values and beliefs on job satisfaction (Fargher et al. 2008).

The results in this paper support the following propositions. First, there is greater rigidity in the structure of work environment in the larger firms. Second, there is also evidence that the large firms are making efforts to overcome the regimentation due to their size by providing job sharing parental leave and working from home. Third, job satisfaction is lower in larger firms as it is often found in the literature. Fourth, observed lower levels of job satisfaction in larger firms may not necessarily

be due to greater regimentation in their structure of working environments. These results may be useful to the managers in the large and small establishments alike.

The conclusions of this paper could be checked with more recent data since there is ongoing change in the structure of working environment in the organizations and in the amenities they offer to their employees especially in the face of the recent digital revolution, globalization and COVID-19. An enormous increase has occurred in the proportion of workers working from home during the COVID-19 pandemic in many countries (Galasso and Faucault, 2020). In the future, post-pandemic period working from home is likely to continue to be the increasingly common form of work arrangement (Barrero, Bloom and Davis, 2021). Kim, Koh and Park (2022) find that during the pandemic working from home has negative effects on the mental health of workers in Korea. The negative effects are greater for women especially for those who carry out both housework and market work. Further, sis could be done in other countries in order to compare the conclusions in different cultural environments. These will be the topics for future studies.

Note: Professor Dr. Saziye Gazioglu was anative of Cyprus where sher grow up. She was very fond of her country and she would go back for visit often. She majored in mathematics for her undergraduate degree at the Middle East Technical University (METU) in Ankara and moved to the UK for her graduate studies. She taught at various Scottish Universities after completing her studies. Her last appointment was at METU in Ankara. Her research interests were varied and ranged from financial economics to labor economics. She had both personal and Professional interest in international migration issues and her writings in this area left a mark in the Professional literature. She was friendly and made many friends at the places where she worked. She is survived. By two sons who live in the UK. She is missed sorely both as a colleague and a friend by many in the UK and in Turkey.

Number of Observations	23 634		23 634		23 634		23 634	

Notes: a: Absolute value of the asymptotic t-ratio.

The critical values at 5 and 1 percent levels of significance are 1.65 and 1.99 respectively.

The likelihood ratio test tests for the joint significance of the work structure variables included. In each case, the statistic is distributed as a chi-square with seven degrees of freedom and is significant at the one percent level. The null hypothesis that the work structure variables are jointly zero is rejected in each case.
