SOEP Survey Papers
Series D – Variable Descriptions and Coding

SOEP-Core v38.1 – BIOBIRTH

Stefan Zimmermann, Claudia Saalbach, and SOEP Group

Running since 1984, the German Socio-Economic Panel (SOEP) is a wide-ranging representative longitudinal study of private households, located at the German Institute for Economic Research, DIW Berlin.

The aim of the SOEP Survey Papers Series is to thoroughly document the survey's data collection and data processing. The SOEP Survey Papers is comprised of the following series:

Series A – Survey Instruments (Erhebungsinstrumente)
Series B – Survey Reports (Methodenberichte)
Series C – Data Documentation (Datendokumentationen)
Series D – Variable Descriptions and Coding
Series E – SOEPmonitors
Series F – SOEP Newsletters
Series G – General Issues and Teaching Materials

The SOEP Survey Papers are available at <http://www.diw.de/soepsurveypapers>

1 Population and purpose of the data set BIOBIRTH

The file BIOBIRTH provides information on fertility histories of adult respondents for the period of panel inclusion in the SOEP. Until 2014 (version 30, wave BD) the data was stored in two separate files: BIOBIRTH containing female fertility histories, and BIOBRTHM providing male fertility histories. Since 2015 (version 31, wave BE) all fertility histories of new respondents as well as the old and continuously updated data of the fertility histories collected in BIOBIRTH (until 2014) and BIOBRTHM (until 2014) are stored in a single file - BIOBIRTH (this naming is identical to the previous fertility histories of women). This dataset contains one row for each person which ever lived in a SOEP household. So BIOBIRTH provide Fertility information on every woman and man who has ever provided at least one successful SOEP Biography interview, but also persons identified as brutto household cases. Therefore, the population of BIOBIRTH in v37 is the same as the population of PPFAD. Precise identification of individuals and their information and respondent status is possible via the variables BIOVALID and BIOINFO. Birth information of persons without a completed SOEP Biography Interview can only be inferred and is estimated via household composition and family relations. The variables BIOVALID and BIOINFO provide information on whether individual level information is based merely on information derived from household composition and family relations, or on biographical questionnaire data. For every respondent a maximum of up to 19 children are considered. The sequence of children within BIOBIRTH is recorded with regards to the birth order in terms of age of the children. The order ranks from the oldest child specified under KIDPNR01 to the youngest child. If the age is missing it is listed in the first record (KIDPNR01), and in subsequent records following KIDPNR01 if more than one child's personal identifier remains missing

2 Sources of information for BIOBIRTH

The main source of information is the individual fertility history collected with the SOEP Biography Instruments, in which the total number of children, birth year and gender of the biological children for every adult respondent are collected. For these adults with information on children stemming from the biography questionnaire the BIOVALID code "31" is assigned. Adults who completed this questionnaire, but did not report any biological children receive the code "30". Since the birth biography from the Biography Questionnaire includes not only biological children but also adopted children, biological children are assumed more frequently for these persons (biovalid = 30). If, in addition to the birth biography from the Biography Questionnaire, Mother-Child questionnaires were also completed in the household, the variable BIOCHILD from the bioagel data set is used to check whether biological parenthood can be assumed. Using this method, the data from the birth biography can be plausibilized and a parent-adoptive child link can be removed. Since respondents can only report a maximum of eight children, there may be an underestimation of the number of children for people with high birth rates. Additional children are added via the household composition in STELL_H from PBRUTTO.

But a large number of respondents did not provide any information on fertility histories by filling in the biographical questionnaire for several reasons. For these cases the variable BIOVALID is assigned the code 10. Nevertheless, in order to make an estimate of fertility for these persons, the current household structure (STELL_H) and other birth information from PBRUTTO are used as the primary source of information for these individuals. This information comes from the survey interviewers and is therefore not a direct response from the respondents. This group is subject to a risk of underestimating the total number of births, particularly since births prior to the entry into the SOEP cannot be identified unless

current household structure provides substantive evidence, usually reflected by parent-child co-residence. Moreover, the household constellation within a SOEP household for persons without a biographical Interview can only be clearly determined for household heads. Since information from the biographical questionnaire is missing in these cases, a final distinction in social and biological children is difficult particular for records considered in earlier SOEP waves when the intra-household relationships (STELL_H) were less refined, compared to the recent setup (since 2011). Therefore parent-child relationships between, for example, the spouse of the household head and children in the household are therefore more likely to be classified as biological parenthood for these groups of persons, although it is also possible that a social parenthood only exists within the household. Hence these older records have a higher likelihood of misspecifying a social as a biological parent-child relationship. Since 2021, the relmatrix dataset has also been used to identify birth parent-child links. As the information in the relmatrix dataset is not related to the head of household, unlike the Stell-code variable, it will be possible to identify parent-child relationships much more reliably from 2021 onward.

Respondents who were over 30 years of age at the time of the first interview, in these cases some of the children are likely to already have left the parental home, and therefore are no longer part of the survey population. For that reason, the number of biological children might be underestimated in this group of respondents to a larger extent as compared to younger women.

The module collecting information on male fertility histories was introduced in 2001. Therefore, most men in subsample “F” (which started in 2000) have completed the birthbiography, since biographical questionnaires are usually completed one wave after the starting wave with only a marginal rate of non-response for this life-course related questionnaire. Note that for men within BIOBIRTH who did not complete a biography questionnaire (BIOVALID code 10), the information about fatherhood is underestimated as only the context of the household is available to determine the respondents biological children. Underestimation of this type is generally more severe for men than for women, since children have a distinctively higher likelihood to co-reside with their mothers after separation, in which case a father will appear to be childless, thus leading to a misspecification as being childless.

3 Identification process of biological children in the SOEP data base

To create BIOBIRTH, the SOEP datasets BIOL, PPFAD, PPATHL, PBRUTTO, RELMATRIX and BIOAGEL are used. In the first step, the loops containing the birth biography information from the dataset BIOL are used and transformed to child level. Since the individual child number is not collected in the biography instrument, the children indicated by the respondent have to be matched with the SOEP population in order to assign an ID to children who are known in the SOEP context. Using PBRUTTO and PPATHL, a parent indicator is generated over the household composition using the STELL_H codes, which attempts to identify birth parent-child relationships in all household years under the given conditions. In addition, since 2021, the relmatrix dataset has also been used to identify birth parent-child links. Since the information in the relmatrix dataset is not related to the head of household, unlike the STELL_H variable, it is possible to identify birth parent-child relationships much more reliably from 2021 onward.

To this created parent pointer dataset, the information from BIOAGEL is added to further identify biological parent-child relationships. If a biological relationship can be ruled out by BIOAGEL, the parent-child link of the parent pointer are resolved.

The variables PZUG and EINTRITT from PBRUTTO are also used to flag new additional births in order to later expand the information from the biographical interview. The variable

PZUG is also used to check over the entire panel history whether biological children ever return to their parents after household abstinence (e.g. stay abroad), so that even children who were not identifiable in the survey year according to the biographical interview receive a correct individual Identifier later in life. After all datasets are created, all information is brought together so that information from the biography interview, parent pointer/household composition, additional births, and children who returned to the household at a later date are usable in one dataset. Since different information has now been merged, information from the biography survey and information from PBRUTTO, for example, may differ. Therefore, a decision indicator is generated that checks which child information is kept, deleted or corrected. The indicator compares in matrix form all possible children (rows) of a parent where the information in the biography interview differs from the information in PBRUTTO. The decision indicator is assembled from:

- Year of birth: $kgeb(BIOL) - gebjahr(PPATHL)$
- Gender: $ksex(BIOL) \neq sex(PPATHL)$
- household status: $kort(BIOL)(\text{at time } t) \neq \text{child in PBRUTTO}(\text{at time } t)$
- number of children: $biokids(BIOL \text{ at time } t) \neq \text{number of children in PBRUTTO}(\text{at time } t)$
- Indicator New birth: birth = “new child was born”
- Is Stellcode combination between parent and child clear or doubtful: 0, 0.5 or 1

An Disparity indicator is created from these individual parameters. If the inequality indicator has exceeded or fallen below the critical value of 2, the following decisions are made:

- Row merge biography information and PBRUTTO information if indicator < 2
- PBRUTTO information is not used child bio stings if indicator ≥ 2

Based on the information from the decision indicator and some other additional information from the data sources, rows ($PBRUTTO \neq BIOL$) are treated as follows:

- row from biography instrument is kept if biography information hardly matches with PBRUTTO information
- row is deleted if biography information probably belongs to a PBRUTTO information
- row is kept if biography information and brutto information match
- PBRUTTO row is kept if a new birth was observed
- PBRUTTO row is kept if corresponding biography row is suspected
- PBRUTTO rows without corresponding biography row (moreover, no birth) is not kept
- For remaining cases, the extent to which the reported number of children differs from the discovered number of children is checked
- If the retained rows match the actual number of children, the rows are retained
- Delete all rows where foster or adopted child is suspected (BIOAGEL info)

- add pbrutto rows of persons with more than eight children because child loop only runs up to 8

After the matching between biography information and brutto household information is complete and only the rows that are considered accurate information are kept, the variable BIOINFO is created. In combination with BIOVALID, this variable can be used to evaluate the quality and accuracy of the BIOBIRTH information provided. A value of “1” ([1] perfect match, bio (self-rep) + brutto (proxy)) is assigned if there is no difference in information from biographical questionnaire and brutto household composition. The variable BIOINFO takes the value “2” ([2] match, bio (self-rep) + brutto (proxy)) as soon as the information of the biography survey differs from the information of the household constellation in brutto. This may occur if there are matching rows but also additional children are born in subsequent years after the biographical survey was conducted. In addition, the code is assigned when there are slight differences in rows between biography and brutto, but these are considered the same information due to a low inequality indicator. In such cases, the brutto information is kept. Due to the small deviation or the plausible change (additional birth in the following year), this information is also of high quality. If an individual could not provide birth biography information (e.g., adolescents or pre-2001 males), a value of “10” is given for BIOVALID and “5” ([5] nomatch, only brutto (proxy)) is given for BIOINFO because only the information from the brutto household composition is available to make an estimate of birth history. This information does not come from the respondent and may therefore be inaccurate.

For individuals where a birth biography is available but the given information differs greatly from the observed information in the household the code “4” ([4] nomatch, only bio (self-rep)) is assigned, the birth biography information is used rather than the brutto household information. In particular, parents with children who no longer live in the parental household and to whom the SOEP has no reference are to be found in this category. The last category “3” ([3] nomatch, bio (self-rep) + brutto (proxy)) describes the cases where the merge process between biography information and brutto information could not find any matches, although information could be found in both information sources. Since the actual birth history is difficult to reconstruct in these cases, the given information from the birth biography is kept because the mismatch indicator is too high.

After bioinfo and biovalid have been defined, the other variables sumkids, biokids, bioyear and bioage are generated. Further information on the generation of the variables can be found in the variable description. The generated variables and the used variables from the birth biography are now reshaped into the wide format, so that one row in the dataset describes the possible parent and the information of the children can be found in the wide format. This completes the generation and BIOBIRTH matches the population of PPFAD and is ready for use.
