Econometric Analysis of High Dimensional VARs Featuring a Dominant Unit

Abstract

This paper extends the analysis of infinite dimensional vector autoregressive models (IVAR) proposed in Chudik and Pesaran (2010) to the case where one of the variables or the cross section units in the IVAR model is dominant or pervasive. This extension is not straightforward and involves several technical difficulties. The dominant unit influences the rest of the variables in the IVAR model both directly and indirectly, and its effects do not vanish even as the dimension of the model (N) tends to infinity. The dominant unit acts as a dynamic factor in the regressions of the non-dominant units and yields an infinite order distributed lag relationship between the two types of units. Despite this it is shown that the effects of the dominant unit as well as those of the neighborhood units can be consistently estimated by running augmented least squares regressions that include distributed lag functions of the dominant unit. The asymptotic distribution of the estimators is derived and their small sample properties investigated by means of Monte Carlo experiments.

A preliminary version of this paper was presented at CEMMAP Workshop on “Cross Section Dependence”, Institute of Fiscal Studies, London, at ECB Workshop on “International Linkages and the Macroeconomy: Applications of GVAR Modelling Approaches”, at CIRANO-CIREQ Conference on “Econometrics of Interactions”, Montreal, and at the University of California, Riverside. We are thankful to the participants at these venues, and to Sean Holly and Marco Lombardi for their helpful comments. The views expressed in this paper are those of the authors and do not necessarily reflect those of the European Central Bank.
1 Introduction

The econometric theory of vector autoregressive (VAR) models is well developed when the dimension of the model \( N \) is small and fixed whilst the number of time series observations \( T \) is large and expanding. This framework, however, is not satisfactory for many empirical applications where both dimensions \( N \) and \( T \) are large. Prominent examples include modelling of regional and national interactions, the panel data analysis of a large number of firms or industries over time. It is clear that without restrictions the parameters of the VAR model can not be consistently estimated in cases where both \( N \) and \( T \) are large, since in such cases the number of unknown parameters grows at a quadratic rate in \( N \). To circumvent this ‘curse of dimensionality’, several techniques have been suggested in the literature that can be broadly characterized as: \( (i) \) data shrinkage, and \( (ii) \) parameter shrinkage. Factor models are examples of the former (see Geweke (1977), Sargent and Sims (1977), Forni and Lippi (2001), Forni et al. (2000), and Forni et al. (2004)). Spatial models, pioneered by Whittle (1954), and further developed by Cliff and Ord (1973), Anselin (1988), and Kelejian and Robinson (1995), and Bayesian type restrictions (e.g. Doan, Litterman, and Sims (1984)) are examples of the latter.

The analysis of infinite dimensional VAR (IVAR) models is considered in Chudik and Pesaran (2010), who propose an alternative solution to the curse of dimensionality based on an \textit{a priori} classification of the units into neighbors and non-neighbors. The coefficients corresponding to the non-neighboring units are restricted to vanish in the limit as \( N \to \infty \), whereas the neighborhood effects are left unrestricted. Neighbors could be individual units or, more generally, linear combinations of the units (such as spatial or local averages). Such limiting restrictions on the parameters of the VAR model turns out to be equivalent to data shrinkage as \( N \to \infty \). Chudik and Pesaran (CP) show that the properties of the IVAR model crucially depend on the extent of the cross section dependence across the units. In the case where such dependencies are weak (in the sense formalized by Chudik, Pesaran and Tosetti (2009)), CP establish that the IVAR model de-couples into separate individual regressions that can be estimated consistently. They also consider the case where the cross section units are strongly correlated, but confine their analysis to situations where the source of strong cross section dependence is external to the model and originate from a finite set of exogenously given factors. For the latter case they propose a cross sectionally augmented least squares (CALS) estimator that they show to be consistent and asymptotically normal.

The present paper extends the analysis of CP to the case where one of the cross section units in the IVAR model is dominant or pervasive, in the sense that it can influence the rest of the system in a way that results in strong cross section dependence.\(^1\) For example in the context of global macroeconomic modelling the assumption that world consists of many small open economies could not be satisfactory since the US economy alone accounts for more than a quarter of world output and, in addition, the US is found to have an important influence on financial markets around the globe, see for example Pesaran, Schuermann, and Weiner (2004). This raises not only the question of how to model the US macroeconomic variables, but also how to model the remaining economies.

\(^1\)Concepts of strong and weak cross section dependence, introduced in Chudik, Pesaran and Tosetti (2009), will be applied to VAR models.
Another example could be the modelling of house prices in different regions in the UK, where developments in London have a large influence on many other regions; see Holly, Pesaran, and Yamagata (2010) for a recent application.

Allowing for the presence of a dominant unit is clearly important, but to date little is known about the estimation of such systems. This paper contributes to the literature in this direction. This extension is not straightforward and involves several technical difficulties. The dominant unit influences the rest of the variables in the IVAR model both directly and indirectly, and its effects do not vanish even as the dimension of the model \((N)\) tends to infinity. The dominant unit acts as a dynamic factor in the regressions of the non-dominant units and yields an infinite order distributed lag relation between the two types of units. Despite this it is shown that the effects of the dominant unit as well as those of the neighborhood units can be consistently estimated by running augmented least square (ALS) regressions that include distributed lag functions of the dominant unit. The asymptotic distribution of the estimators is derived and their small sample properties investigated by means of Monte Carlo experiments.

The remainder of this paper is organized as follows. Section 2 sets up the IVAR model with a dominant unit. Section 3 derives infinite order moving average or autoregressive approximations for the cross section units and discusses the conditions under which the IVAR model yields a dynamic factor model with the dominant unit acting as the factor. The asymptotic distribution of the ALS estimator is derived and discussed in Section 4. Section 5 investigates finite sample properties of the ALS estimator by means of Monte Carlo experiments. Section 6 provides some concluding remarks. Selected proofs and other technical details are given in the Appendix.

Notations: \( \|A\|_1 \equiv \max_{1 \leq i \leq N} \sum_{j=1}^N |a_{ij}| \) denotes the column matrix norm of the \(N \times N\) matrix \(A\), \( \|A\|_\infty \equiv \max_{1 \leq j \leq N} \sum_{i=1}^N |a_{ij}| \) is the row matrix norm of \(A\). \( \|A\| = \sqrt{\varrho (A^TA)} \) is the spectral norm of \(A\), where \(\varrho (A)\) is the spectral radius of \(A\).\(^2\) All vectors are column vectors. The \(i^{th}\) row of \(A\) with its \(i^{th}\) element replaced by 0 is denoted by \(a'_{-i} = (a_{i1}, a_{i2}, \ldots, a_{i,i-1}, 0, a_{i,i+1}, \ldots, a_{i,N})\). The \(i^{th}\) row of \(A\) with its first and \(i^{th}\) elements replaced by 0 is denoted by \(a'_{-i-1,i} = (0, a_{i2}, \ldots, a_{i,i-1}, 0, a_{i,i+1}, \ldots, a_{i,N})\). \(a_1 = (a_{11}, a_{21}, \ldots, a_{N1})^T\) denotes the first column vector of \(A\). A matrix constructed from \(A\) by replacing its first column by a column vector of zeros is denoted as \(A_{-1}\). \(\|x_t\|_{\ell_p}\) is \(L_p\)-norm of a random variable \(x_t\), defined as \((E|x_t|^p)^{1/p}\). \((N,T) \overset{\mathcal{J}}{\sim} \infty\) denotes joint asymptotics in \(N\) and \(T\), with \(N\) and \(T \to \infty\), in no particular order. \(a_n = O(b_n)\) denotes that the deterministic sequence \(\{a_n\}\) is at most of order \(b_n\). \(x_n = O_p(y_n)\) states that random variable \(x_n\) is at most of order \(y_n\) in probability. \(\mathbb{R}\) is the set of real numbers, \(\mathbb{N}\) is the set of natural numbers, and \(\mathbb{Z}\) is the set of integers. Convergence in distribution and convergence in probability are denoted by \(\overset{d}{\rightarrow}\) and \(\overset{p}{\rightarrow}\), respectively. Convergence in quadratic mean, and convergence in \(L_1\) norm are denoted by \(\overset{qm}{\rightarrow}\) and \(\overset{L_1}{\rightarrow}\), respectively. We use \(K\) and \(\rho\) to denote positive real numbers that do not vary with \(N\) and/or \(T\).

\(^2\)Note that if \(x\) is a vector, then \(\|x\| = \sqrt{\varrho (x^Tx)} = \sqrt{x^Tx}\) corresponds to the Euclidean length of vector \(x\).
2 The IVAR Model with a Dominant Unit

Suppose we have $T$ time series observations on $N$ cross section units indexed by $i \in S(N) \equiv \{ 1, \ldots, N \} \subseteq \mathbb{N}$. Both dimensions, $N$ and $T$, are assumed to be large. For each point in time, $t$, and for each $N \in \mathbb{N}$, the $N$ cross section observations are collected in the $N$ dimensional vector, $x_{(N),t} = (x_{(N),1t}, x_{(N),2t}, \ldots, x_{(N),Nt})'$, and it is assumed that $x_{(N),t}$ follows the VAR(1) model

$$x_{(N),t} = \Phi_{(N)} x_{(N),t-1} + u_{(N),t},$$

(1)

where $\Phi_{(N)}$ is an $N \times N$ matrix of unknown coefficients and $u_{(N),t}$ is an $N \times 1$ vector of error terms. To distinguish high dimensional VAR models from the standard specifications we refer to the sequence of VAR models (1) of growing dimensions ($N \rightarrow \infty$) as the infinite dimensional VARs or IVARs for short.3 The extension of the IVAR(1) to the $p^{th}$ order IVAR model where $p$ is fixed, is relatively straightforward and will not be attempted in this paper.

The explicit dependence of the variables and the parameters of the IVAR model on $N$ is suppressed in the remainder of the paper to simplify the notations, but it will be understood that in general they vary with $N$, unless stated otherwise. In what follows we shall also focus on the problem of estimation of the parameters of individual units in (1). In particular, we consider the equation for the $i^{th}$ unit that we write as

$$x_{it} = \sum_{j=1}^{N} \phi_{ij} x_{jt-1} + u_{it}, \quad \text{for } t = 1, 2, \ldots, T.$$  

(2)

Clearly, it is not possible to estimate all the $N$ coefficients $\phi_{ij}$, $j = 1, \ldots, N$, when $N$ and $T$ grow at the same rate, unless suitable restrictions are placed on some of the coefficients. One such restriction is the ‘cross section absolute summability condition’,

$$\sum_{j=1}^{N} |\phi_{ij}| < K \text{ for any } N \in \mathbb{N} \text{ and any } i \in \{ 1, \ldots, N \},$$

(3)

which ensures that the variance of $x_{it}$ conditional on information available at time $t - \ell$, for any fixed $\ell > 0$, exits for all $N$ and as $N \rightarrow \infty$. The Lasso and Ridge shrinkage methods also use similar constraints.4 Condition (3) implies that many of the coefficients are infinitesimal (as $N \rightarrow \infty$). However, assuming a mere existence of an upper bound $K$ in (3) need not be sufficient to deal with the dimensionality problem and we impose additional restrictions below. We follow CP and suppose that in addition to (3), it is possible, for each $i \in \mathbb{N}$, to divide the units into ‘neighbors’

3The sequence of models obtained from (1) for different values of $N$ is compatible with both cases where $\text{cov} (x_{(N),it}, x_{(N),jt})$ changes with $N$ or is invariant to $N$. We allow for both possibilities since in some applications the covariance between individual units could change with the inclusion of a new unit - as it is likely to be the case when modelling firms or assets within expanding markets. For further details see Chudik and Pesaran (2010).

4These ‘data mining’ methods attempt at estimating all the unknown coefficients of the $i^{th}$ equation, $\phi_{ij}$, $j = 1, \ldots, N$, by minimizing $\sum_{t=1}^{T} u_{it}^2$ subject to $\sum_{j=1}^{N} |\phi_{ij}| \leq K$ (Lasso) or $\sum_{j=1}^{N} \phi_{ij}^2 \leq K$ (Ridge). But the outcome, perhaps not surprisingly, only yields a relatively small number of non-zero estimates. See Chapter 3.4.3 of Hastie, Tibshirani, and Friedman (2001) for detailed descriptions of Lasso and Ridge regression shrinkage methods.
and ‘non-neighbors’. But depart from CP by allowing one of the units, which we take to be the first unit without loss of generality, to be dominant or pervasive in the sense to be made precise below. Also given our focus, to simplify the analysis we abstract from the effects of other neighbors apart form that of the dominant unit and own lags. In a dynamic sense the lagged value of the \( i^{th} \) unit can also be viewed as the \( i^{th} \) neighbor.

**ASSUMPTION 1** *(Neighbors and non-neighbors)* The neighbors of unit \( i \) are units 1 and \( i \), and the remaining units are non-neighbors. That is, the following conditions are satisfied. Coefficients corresponding to neighbors, namely \( \phi_{i1} \) and \( \phi_{ii} \), for \( i = 1, 2, \ldots \), do not change with \( N \). There exists a constant \( K < \infty \) (independent of \( i \) and \( N \)) such that the coefficients corresponding to neighbors satisfy \( |\phi_{ii}| < K, |\phi_{i1}| < K \), for all \( i \in \mathbb{N} \),

\[
\sum_{i=1}^{N} |\phi_{i1}| = O(N), \tag{4}
\]

and the coefficients corresponding to non-neighbors satisfy

\[
\|\phi_{-1}\|_{\infty} = \max_{j \in \{2, \ldots, N\}} |\phi_{1j}| < \frac{K}{N}, \tag{5}
\]

and

\[
\|\phi_{-1,-i}\|_{\infty} = \max_{j \in \{2, \ldots, N\} \setminus \{i\}} |\phi_{ij}| < \frac{K}{N}, \tag{6}
\]

for any \( N \in \mathbb{N} \) and any \( i \in \{2, 3, \ldots, N\} \), where \( \phi_{-1} = (0, \phi_{12}, \phi_{13}, \ldots, \phi_{1N})' \) and \( \phi_{-1,-i} = (0, \phi_{i2}, \ldots, \phi_{i,i-1}, 0, \phi_{i,i+1}, \ldots, \phi_{iN})' \).

The division of units in Assumption 1 imposes sufficient number of constraints that allows us to tackle the dimensionality problem. Consider the problem of estimation of the unknown coefficient \( \phi_{ii} \). We have

\[
x_{it} = \phi_{ii} x_{i,t-1} + \phi_{i1} x_{1,t-1} + \sum_{j \neq 1,i} \phi_{ij} x_{j,t-1} + u_{it}, \tag{7}
\]

for \( i = 2, 3, \ldots, N \), and the estimation of the neighboring coefficients, \( \phi_{ii} \) and \( \phi_{11} \), depends on the stochastic behavior of the cross section average \( \sum_{j \neq 1,i} \phi_{ij} x_{j,t-1} \), which captures the aggregate spatiotemporal impact of non-neighbors. CP shows that if \( \{x_{it}\} \) is cross sectionally weakly dependent, then the aggregate impact of non-neighbors \( \sum_{i=1}^{n} \phi_{ii} x_{i,t-1} \) is cross sectionally strongly dependent. In the case of strong cross section dependence, the aggregate impact of non-neighbors is \( O_p(1) \), and it will not be possible to consistently estimate the coefficients of the neighboring units by ignoring the non-neighborhood effects.

The coefficients in the first column of matrix \( \Phi \) correspond to the direct lagged impact of unit 1 on the rest of the system. The pervasive nature of unit 1 as characterized by (4) represents an
important departure from the set up in CP, where the influence of any of the cross section units on the rest of the system is restricted by assumption \( \| \Phi \| < K \). In this paper \( \| \Phi \| \) is allowed to be unbounded in \( N \), but only through the dominant effect of unit 1.

Similar considerations also apply to contemporaneous dependence of the units through the error terms, \( u_t = (u_{1t}, u_{2t}, ..., u_{Nt})' \). Let

\[
u_t = R \varepsilon_t,\]

where \( R \) is the \( N \times N \) matrix of non-stochastic coefficients, and \( \varepsilon_t = (\varepsilon_{1t}, \varepsilon_{2t}, ..., \varepsilon_{Nt})' \) is an \( N \times 1 \) vector of random variables. This formulation is quite general and includes all models of spatial dependence considered in the literature, where it is assumed that \( R \) has bounded row and column matrix norms.\(^5\) In the assumption below we relax this condition and allow for the first column of \( R \) to be unbounded.

**ASSUMPTION 2** (Error terms and contemporaneous dominance) The contemporaneous dependence of the errors \( u_t = (u_{1t}, u_{2t}, ..., u_{Nt})' \) in (1) is characterized by (8), where the individual elements of the double index array \( \{\varepsilon_{it}, i \in \mathbb{N}, t \in \mathbb{Z}\} \) are independently distributed with mean 0, finite variances, and finite fourth moments uniformly bounded in \( i \in \mathbb{N} \). Consider the decomposition of \( R \)

\[
R = r_1 s_1' + R_{-1},
\]

where \( r_1 = (r_{11}, r_{21}, ..., r_{N1})' \) is the first column of \( R \), coefficients in \( r_1 \) do not change with \( N \), \( s_1 \) is an \( N \times 1 \) selection vector, \( s_1 = (1, 0, ..., 0)' \), and \( R_{-1} \) is obtained from \( R \) by replacing its first column with a vector of zeros. Assume that \( r_{ii} = 1 \) for all \( i \in \mathbb{N} \) (without the loss of generality) and that there exists a constant \( K < 1 \) (independent of \( i \) and \( N \)) such that

\[
\text{Var} (\varepsilon_{it}) = \sigma_{\varepsilon_{it}}^2 < K,
\]

\[\|R_{-1}\|_1 < K, \quad \|R_{-1}\|_\infty < K,\]

and

\[
\|r_{-1}\|_\infty = \max_{j \in \{2, ..., N\}} |r_{1j}| < \frac{K}{N},
\]

for any \( N \in \mathbb{N} \), where \( r_{-1} = (0, r_{12}, r_{13}, ..., r_{1N})' \) is the \( N \times 1 \) column vector constructed from the first row of \( R_{-1} \). In addition, \( |r_{1i}| < K \), for all \( i \in \mathbb{N} \), and

\[
\sum_{i=1}^{N} |r_{1i}| = O(N).
\]

Under this assumption the error of the first cross section unit acts as a (static) common factor for the rest of the units. Condition (13) allows for the first cross section unit to have a dominant effect on all the other cross section units. The boundedness of \( R_{-1} \) ensures that no other cross section units has a dominant effect on the rest of the units.

\(^5\)See Pesaran and Tosetti (2009) for further details.
The above set up can be generalized to two or more dominant units so long as the number of such units is fixed and does not change with \( N \). In this paper we focus on IVAR models with one dominant unit and assume that the dominant unit is known \textit{a priori}. The analysis of models with more than one dominant units and the problem of how to identify such units will be outside the scope of the present paper.

3 Large \( N \) Representations

The presence of a dominant unit in the IVAR model considerably complicates the analysis. This is because the effects of the dominant unit show up in all other units both contemporaneously as well as being distributed over time in the form of infinite order moving average or autoregressive representations. For empirical analysis it is important that conditions under which such infinite order processes can be well approximated by time series models with a finite number of unknown parameters are met. To this end we introduce a number of further assumptions restricting the behavior of \( \Phi \) and \( R \) for a finite \( N \) as well as when \( N \to \infty \).

**ASSUMPTION 3** (Starting values and stationarity) Available observations are \( x_0, x_1, \ldots, x_T \) with \( x_0 = \sum_{\ell=0}^{\infty} \Phi^\ell u(-\ell) \), and there exists a real positive constant \( \rho < 1 \) (independent of \( N \)) such that for any \( N \in \mathbb{N} \)

\[
|\lambda_1(\Phi)| \leq \rho. \tag{14}
\]

**ASSUMPTION 4** (Bounded variances and invertibility of large \( N \) ARMA representations) Similarly to (9) let

\[
\Phi = \phi_1 s_1 + \Phi_{-1}, \tag{15}
\]

where \( \Phi_{-1} \) is obtained from \( \Phi \) by replacing its first column with a column of zeros and \( \phi_1 \) is the first column of \( \Phi \). Assume that there exists a real positive constant \( \rho < 1 \) (independent of \( N \)) such that for any \( N \in \mathbb{N} \):

\[
\|\Phi_{-1}\|_1 \leq \rho, \quad \|\Phi_{-1}\|_{\infty} \leq \rho, \tag{16}
\]

and

\[
\|\phi_1\|_{\infty} = \max_{1 \leq i \leq N} |\phi_{i1}| \leq \rho. \tag{17}
\]

Furthermore,

\[
\max_{i \in \mathbb{N}} |r_{i1}| \leq 1. \tag{18}
\]

**Remark 1** Condition (14) of Assumption 3 is a well known sufficient condition for covariance stationarity for any fixed \( N \in \mathbb{N} \). This condition, however, is not sufficient for \( \text{Var}(x_{it}) \) to remain bounded as \( N \to \infty \). As shown in Chudik and Pesaran (2010), \( \|\Phi\| \leq \rho < 1 \) would be sufficient for bounded variances (as \( N \to \infty \)), but in our set-up \( \|\Phi\| \) is unbounded due to the presence of a dominant unit in the IVAR model. Assumption 4 provides additional sufficient conditions for bounded variances (as \( N \to \infty \)) and also for the existence of an invertible large \( N \) AR(\( \infty \)) and MA(\( \infty \)) processes for the dominant unit.
Using the notations introduced in Assumptions 2 and 4 (see equations (9) and (15)), model (1) can be written as

\[
x_t = (\phi_1 s_1^t + \Phi_{-1}) x_{t-1} + (r_1 s_1^t + R_{-1}) \varepsilon_t,
\]

where

\[
e_t = R_{-1} \varepsilon_t.
\]

Solving for \( x_t \) by backward substitution yields

\[
x_t = \sum_{\ell=0}^{\infty} \Phi_{-1}^\ell \phi_1 x_{1,t-1-\ell} + \sum_{\ell=0}^{\infty} \Phi_{-1}^\ell r_1 \varepsilon_{1,t-\ell} + v_t,
\]

where

\[
v_t = \sum_{\ell=0}^{\infty} \Phi_{-1}^\ell e_{t-\ell}.
\]

**Lemma 1** Suppose Assumptions 2-4 hold. Then for any \( N \times 1 \) vector \( \mathbf{a} \) satisfying condition \( \| \mathbf{a} \| = O \left( N^{-1/2} \right) \) we have

\[
Var (\mathbf{a}' v_t) = Var \left( \mathbf{a}' \sum_{\ell=0}^{\infty} \Phi_{-1}^\ell e_{t-\ell} \right) = O \left( N^{-1} \right),
\]

where \( v_t \) is defined by (22).

**Proof.**

\[
Var (\mathbf{a}' v_t) = \| Var (\mathbf{a}' v_t) \| = \left\| \sum_{\ell=0}^{\infty} \mathbf{a}' \Phi_{-1}^\ell R_{-1} Var (\varepsilon_{t-\ell}) \Phi_{-1}^\ell \mathbf{a} \right\|,
\]

\[
\leq \| \mathbf{a} \|^2 \| R_{-1} \|^2 \sum_{\ell=0}^{\infty} \| \Phi_{-1} \|^2 \| Var (\varepsilon_{t-\ell}) \|.
\]

But \( \| R_{-1} \|^2 \leq \| R_{-1} \| \| R_{-1} \|_1 = O (1) \) by condition (11) of Assumption 2, \( \| Var (\varepsilon_{t-\ell}) \| < K \) (for any \( \ell = 0, 1, 2, \ldots \)) by condition (10) of Assumption 2, \( \| \mathbf{a} \|^2 = O \left( N^{-1} \right), \| \Phi_{-1} \| \leq \sqrt{\| \Phi_{-1} \|_1 \| \Phi_{-1} \|_\infty} \leq \rho \) by condition (16) of Assumption 4 and \( \sum_{\ell=0}^{\infty} \| \Phi_{-1} \|^2 \leq \sum_{\ell=0}^{\infty} \rho^{2\ell} < K \). Hence, \( \| Var (\mathbf{a}' v_t) \| = O \left( N^{-1} \right) \), as required.

Lemma 1 establishes that \( v_t \) is cross sectionally weakly dependent (CWD), and in particular \( \mathbf{a}' v_t = O_p \left( N^{-1/2} \right) \) for any vector \( \mathbf{a} \) satisfying \( \| \mathbf{a} \| = O \left( N^{-1/2} \right) \). For the non-dominant units, \( i > 1 \), using (21) we have

\[
x_{it} = d_i (L) x_{1,t-1} + b_i (L) \varepsilon_{1t} + v_{it},
\]

where \( v_{it} = s_i^t v_t \),

\[
d_i (L) = \sum_{\ell=0}^{\infty} \left( s_i^t \Phi_{-1}^\ell \phi_1 \right) L^\ell,
\]
and \( \mathbf{s}_i \) is an \( N \times 1 \) dimensional selection vector with \( s_{ij} = 0 \) for \( j \neq i \) and \( s_{ii} = 1 \). In the case of the dominant unit \( (i = 1) \) equation (21) yields,

\[
c(L)x_{it} = b_1(L)\varepsilon_{1t} + v_{1t},
\]

where

\[
b_1(L) = \sum_{\ell=0}^{\infty} \left( \mathbf{s}_1' \Phi_{\ell-1} \mathbf{r}_1 \right) L^\ell,
\]

\[
c(L) = 1 - d_1(L) = 1 - \sum_{\ell=0}^{\infty} \left( \mathbf{s}_1' \Phi_{\ell-1} \phi_1 \right) L^{\ell+1},
\]

and \( v_{1t} = \mathbf{s}_1' \mathbf{v}_t \). Note that \( v_{1t} \) can be written as

\[
v_{1t} = \sum_{\ell=0}^{\infty} \mathbf{s}_1' \Phi_{\ell-1} \mathbf{e}_{t-\ell} = e_{1t} + \sum_{\ell=1}^{\infty} \mathbf{s}_1' \Phi_{\ell-1} \mathbf{e}_{t-\ell}
\]

\[
= e_{1t} + \mathbf{s}_1' \Phi_{-1} \sum_{\ell=1}^{\infty} \Phi_{\ell-1} \mathbf{e}_{t-\ell}.
\]

But \( \mathbf{s}_1' \Phi_{-1} = \phi'_{-1} \), and

\[
\sum_{\ell=1}^{\infty} \Phi_{\ell-1} \mathbf{e}_{t-\ell} = \sum_{\ell=0}^{\infty} \Phi_{\ell-1} \mathbf{e}_{t-\ell-1} = \mathbf{v}_{t-1}.
\]

Hence

\[
v_{1t} = e_{1t} + \phi'_{-1} \mathbf{v}_{t-1}.
\]

Also it is easily seen that \( e_{1t} = \mathbf{s}_1' \mathbf{R}_{-1} \varepsilon_t = \mathbf{r}'_{-1} \varepsilon_t \), and \( \mathbf{v}_{t-1} = \sum_{\ell=1}^{\infty} \Phi_{\ell-1} \mathbf{R}_{-1} \varepsilon_{t-\ell} \) both have zero means and are uncorrelated. Therefore

\[
\text{Var}(v_{1t}) = \text{Var}(\mathbf{r}'_{-1} \varepsilon_t) + \text{Var}(\phi'_{-1} \mathbf{v}_{t-1}) = O\left(N^{-1}\right),
\]

where

\[
\text{Var}(\mathbf{r}'_{-1} \varepsilon_t) = \mathbf{r}'_{-1} \text{Var}(\varepsilon_t) \mathbf{r}_{-1} \leq ||\mathbf{r}_{-1}||^2 ||\text{Var}(\varepsilon_t)||,
\]

\[
||\mathbf{r}_{-1}||^2 \leq ||\mathbf{r}_{-1}||_{\infty} ||\mathbf{r}_{-1}||_1 = O\left(N^{-1}\right) \text{ by (12) of Assumption 2, } ||\text{Var}(\varepsilon_t)|| < K \text{ by condition (10) of Assumption 2, and } \text{Var}(\phi'_{-1} \mathbf{v}_{t-1}) = O\left(N^{-1}\right) \text{ follows from Lemma 1 by setting } a = \phi_{-1} \text{ and noting that } ||\phi_{-1}|| \leq \sqrt{||\phi_{-1}||_{\infty} ||\phi_{-1}||_1} = O\left(N^{-1/2}\right) \text{ by condition (5) of Assumption 1. Therefore, since } E(v_{1t}) = 0, \text{ then}
\]

\[
v_{1t} = O_p\left(N^{-1/2}\right),
\]

and equation (27) can be written as

\[
c(L)x_{1t} = b_1(L)\varepsilon_{1t} + O_p\left(N^{-1/2}\right),
\]

\[9\]
which is a large $N$ ARMA$(\infty, \infty)$ representation of the process for the dominant unit.

The next lemma establishes invertibility of polynomials $b_1(L)$ and $c(L)$.

**Lemma 2** Suppose Assumption 4 holds. Then inverses of the polynomials $b_1(L)$ and $c(L)$, defined by (28) and (29), respectively, exist for any $N \in \mathbb{N}$, and coefficients of polynomials $b_1^{-1}(L)$ and $c^{-1}(L)$ decay at an exponential rate uniformly in $N$. Also, there exist real positive constants $K < \infty$ and $\rho < 1$ such that

$$|a_\ell| < K \rho^\ell, \text{ for any } \ell \in \{0, 1, 2, \ldots\} \text{ and any } N \in \mathbb{N},$$

where

$$a(L) = \sum_{\ell=0}^\infty a_\ell L^\ell = b_1^{-1}(L) c(L).$$

**Proof.** Coefficients of the polynomial $c(L) = \sum_{\ell=0}^\infty c_\ell L^\ell$, as defined by equation (29), satisfy: $c_0 = 1$, and $|c_\ell| = |s_1' \Phi_{-1} \phi_1| \leq \| \Phi_{-1} \|_\infty \| \phi_1 \|_\infty$ for any $\ell \in \mathbb{N}$. Conditions (16) and (17) of Assumption 4 postulate that $\| \Phi_{-1} \|_\infty \leq \rho < 1$ and $\| \phi_1 \|_\infty \leq \rho < 1$, which implies that $|c_\ell| \leq \rho^\ell$ for any $\ell \in \mathbb{N}$. Invertibility of $c(L)$ and exponential decay of the coefficients in $c^{-1}(L)$ now directly follows from Lemma A.1. Exponential decay of the coefficients in $c^{-1}(L)$ is uniform in $N$, because $\rho$ does not depend on $N \in \mathbb{N}$.

Coefficients of the polynomial $b_1(L) = \sum_{\ell=0}^\infty b_1 \ell L^\ell$, as defined by equation (28), satisfy $b_10 = 1$, and $|b_1 \ell| = |s_1' \Phi_{-1} r_1| \leq \| \Phi_{-1} \|_\infty \| r_1 \|_\infty$ for any $\ell \in \mathbb{N}$. Conditions (16) and (18) of Assumption 4 imply $\| \Phi_{-1} \|_\infty \| r_1 \|_\infty \leq \rho^\ell$, which establishes $|b_1 \ell| \leq \rho^\ell$ for any $\ell \in \mathbb{N}$. Invertibility of $b_1(L)$ and the exponential decay of the coefficients in $b_1^{-1}(L)$ now follows from Lemma A.1. Similarly to $c^{-1}(L)$, the coefficients of $b_1^{-1}(L)$ exponentially decay uniformly in $N \in \mathbb{N}$.

Noting that $|c_\ell| \leq \rho^\ell$ for any $\ell = 0, 1, 2, \ldots$, and that the coefficients of $b_1^{-1}(L)$ decay exponentially, it follows that the coefficients of $a(L) = b_1^{-1}(L) c(L)$ must also decay at an exponential rate. This completes the proof. ■

It is worth noting that conditions $\| \Phi_{-1} \|_\infty \leq \rho < 1$ and $\| \phi_1 \|_\infty \leq \rho < 1$ of Assumption 4 are sufficient to ensure that $c(L)$ is invertible and the coefficients of $c^{-1}(L)$ decay exponentially. On the other hand conditions $\| \Phi_{-1} \|_\infty \leq \rho < 1$ and $\max_{i \in \mathbb{N}} |r_{1i}| \leq 1$, are sufficient in ensuring that $b_1(L)$ is invertible and the coefficients of $b_1^{-1}(L)$ decay exponentially. The exponential decay of the coefficients in these polynomials will be relevant for the selection of truncation lags in empirical applications as discussed below.

### 3.1 Large $N$ AR and MA representations for the dominant unit

Multiplying both sides of (27) by $b_1^{-1}(L)$ we obtain

$$a(L)x_{1t} = \varepsilon_{1t} + \vartheta_{bt},$$

(36)
where $\vartheta_{bt} = b_1^{-1} (L) v_{1t}$. By Lemma 2 the coefficients of $b_1^{-1} (L)$ decay exponentially and hence are absolute summable, and in view of (31) we have

$$Var (\vartheta_{bt}) = O \left( N^{-1} \right).$$

(37)

Also since $E (\vartheta_{bt}) = 0$, it follows that

$$\vartheta_{bt} = b_1^{-1} (L) v_{1t} = O_p \left( N^{-1/2} \right).$$

(38)

Using this result in (36) yields the following large $N$ AR($\infty$) representation for the dominant unit,

$$a (L) x_{1t} = \varepsilon_{1t} + O_p \left( N^{-1/2} \right).$$

(39)

Similarly, multiplying both sides of (27) by $c_1^{-1} (L)$ we obtain

$$x_{1t} = a_1^{-1} (L) \varepsilon_{1t} + \vartheta_{ct},$$

(40)

where $a_1^{-1} (L) = c_1^{-1} (L) b_1 (L)$, and $\vartheta_{ct} = c_1^{-1} (L) v_{1t}$. Using similar arguments as in derivation of (37)

$$Var (\vartheta_{ct}) = O \left( N^{-1} \right),$$

(41)

and since $E (\vartheta_{ct}) = 0$, then

$$\vartheta_{ct} = c_1^{-1} (L) v_{1t} = O_p \left( N^{-1/2} \right),$$

(42)

and we have the following large $N$ MA($\infty$) representation for $x_{1t}$,

$$x_{1t} = a_1^{-1} (L) \varepsilon_{1t} + O_p \left( N^{-1/2} \right).$$

(43)

### 3.2 Large $N$ representation for the non-dominant units $i > 1$

Consider now the equation for unit $i > 1$. Using (1) we have (noting that $u_{it} = r_{i1} \varepsilon_{1t} + \varepsilon_{it}$)

$$x_{it} = \phi_{ii} x_{i,t-1} + \phi_{i-1,-i} x_{t-1} + \phi_{i1} x_{1,t-1} + r_{i1} \varepsilon_{1t} + \varepsilon_{it}.$$  

(44)

Multiplying both sides of (21) by $\phi'_{i-1,-i}$ yields

$$\phi'_{i-1,-i} x_t = p_i (L) x_{1,t-1} + k_i (L) \varepsilon_{1t} + \phi'_{i-1,-i} v_t,$$

(45)

where

$$p_i (L) = \sum_{\ell=0}^{\infty} \left( \phi'_{i-1,-i} \Phi_{i-1}^\ell \phi_1 \right) L^\ell,$$

(46)

and

$$k_i (L) = \sum_{\ell=0}^{\infty} \left( \phi'_{i-1,-i} \Phi_{i-1}^\ell r_1 \right) L^\ell.$$ 

(47)
Substituting (45) in (44) and using (27) to eliminate $\varepsilon_{1t}$ from (44) we have
\[ x_{it} = \phi_{i} x_{i,t-1} + \beta_i (L) x_{1t} + e_{it} + \zeta_{it}, \] (48)
where
\[ \beta_i (L) = \phi_{1i} L + \rho_i (L) L^2 + [r_{i1} + k_i (L) L] a (L), \] (49)
and
\[ \zeta_{it} = \phi_{t-1,-i} v_{t-1} - [r_{i1} + k_i (L) L] \theta_{it}. \] (50)
Taking $L_2$-norm of (50) and using triangle inequality we obtain
\[ \| \zeta_{it} \|_{L_2} \leq \| \phi_{t-1,-i} v_{t-1} \|_{L_2} + \| [r_{i1} + k_i (L) L] \theta_{it} \|_{L_2}. \] (51)
But under condition (6) in Assumption 1, we have $\| \phi_{t-1,-i} \|_\infty = O \left( N^{-1} \right)$ uniformly in $i \in \{2,3,\ldots\}$, which implies that $\| \phi_{t-1,-i} \| = O \left( N^{-1/2} \right)$, and it follows from Lemma 1 (by setting $a = \phi_{1,-i}$) that
\[ \text{Var} (\phi_{t-1,-i} v_{t-1}) = O \left( N^{-1} \right), \text{ uniformly in } i \in \{2,3,\ldots\}, \]
and (noting that $E (\theta_{it}) = 0$)
\[ \| \phi_{t-1,-i} v_{t-1} \|_{L_2} = O \left( N^{-1/2} \right), \text{ uniformly in } i \in \{2,3,\ldots\}. \] (52)
Also by (37) and noting that the coefficients of $k_i (L)$ decay exponentially to zero uniformly in $i \in \{2,3,\ldots\}$ (see proof of Lemma 3 below) and $E (\theta_{it}) = 0$, we have
\[ \| [r_{i1} + k_i (L) L] \theta_{it} \|_{L_2} = O \left( N^{-1/2} \right), \text{ uniformly in } i \in \{2,3,\ldots\}. \] (53)
Using (52) and (53) in (51) and noting that $E (\zeta_{it}) = 0$, we have
\[ \text{Var} (\zeta_{it}) = \| \zeta_{it} \|_{L_2}^2 = O \left( N^{-1} \right), \text{ uniformly in } i \in \{2,3,\ldots\}, \] (54)
and
\[ \zeta_{it} = O_p \left( N^{-1/2} \right), \text{ uniformly in } i \in \{2,3,\ldots\}. \] (55)
Hence, the large $N$ representation of the process for the non-dominant unit $i > 1$ is given by
\[ x_{it} = \phi_{i} x_{i,t-1} + \beta_i (L) x_{1t} + e_{it} + O_p \left( N^{-1/2} \right). \] (56)
It is valid to exclude the contemporaneous values of $x_{1t}$ from (56) if and only if $r_{i1} = 0$, for $i > 1$. However, $x_{1,t-1}$ enters the regression equation for the $i^{th}$ unit even if $r_{i1} = \phi_{i1} = 0$. Note also that in general the polynomial $\beta_i (L)$ is of infinite order, and the errors, $e_{it}$, are serially uncorrelated but cross sectionally weakly dependent.

**Lemma 3** Suppose Assumption 4 holds. Then there exist real positive constants $K < \infty$ and...
\[ |\beta_{i\ell}| < K \rho^\ell \text{ for any } \ell \in \{0, 1, 2, \ldots\}, \text{ any } N \in \mathbb{N} \text{ and any } i \in \{1, 2, \ldots, N\}, \tag{57} \]

where \( \beta_{i\ell} \) is defined by the coefficients of polynomial \( \beta_i(L) = \sum_{\ell=0}^{\infty} \beta_{i\ell} L^\ell \) in (49).

**Proof.** Existence of real positive constants \( K < \infty \) and \( 0 < \rho < 1 \) (independent of \( N \)) such that \( |a_\ell| < K \rho^\ell \) was established in Lemma 2. Coefficients of polynomials \( p_i(L) = \sum_{\ell=0}^{\infty} p_{i\ell} L^\ell \) and \( k_i(L) = \sum_{\ell=0}^{\infty} k_{i\ell} L^\ell \), as defined by equations (46) and (47), respectively, satisfy:

\[ |p_{i\ell}| \leq \left\| \phi'_{i-1,-i} \Phi_{i-1} \phi_1 \right\|_\infty < K \rho^\ell, \text{ and } |k_{i\ell}| \leq \left\| \phi'_{i-1,-i} \Phi_{i-1} r_1 \right\|_\infty < K \rho^\ell, \tag{58} \]

where \( \left\| \phi'_{i-1,-i} \right\|_\infty = \sum_{j \neq 1, i} |\phi_{ij}| < K \) by (6) of Assumption 1, \( \left\| \Phi_{i-1} \right\|_\infty \leq \rho^\ell < 1 \) by (16) of Assumption 4, \( \left\| \phi_1 \right\|_\infty \leq \rho < 1 \) by (17) of Assumption 4, and \( \|r_1\|_\infty = \max_{i=1,\ldots,N} |r_{i1}| \leq 1 \) by (18) of Assumption 4. Result (57) now directly follows by noting that linear combinations and products of polynomials with exponentially decaying coefficients are also polynomials with exponentially decaying coefficients. \( \blacksquare \)

### 4 Asymptotic Distribution of the Augmented Least Squares Estimator

#### 4.1 Specification of Augmented Regressions

Based on the large \( N \) representation (39) for the dominant unit, and the representation (56) for the non-dominant units \( (i > 1) \), we consider the following regressions:

\[
x_{it} = g'_{it} \pi_i + \epsilon_{it}, \text{ for } i = 1, 2, \ldots, N, \tag{59} \]

where

\[
g_{it} = \begin{cases} (x_{1,t-1}, x_{1,t-2}, \ldots, x_{1,t-m})', & \text{for } i = 1 \\ (x_{i,t-1}, x_{i,t-1}, \ldots, x_{1,t-m})', & \text{for } i > 1 \end{cases} \tag{60} \]

\[
\pi_i = \begin{cases} (a_1, a_2, \ldots, a_m)', & \text{for } i = 1 \\ (\phi_{ii}, \beta_{i0}, \beta_{i1}, \ldots, \beta_{im})', & \text{for } i > 1 \end{cases} \tag{61} \]

\[
\epsilon_{it} = \begin{cases} \psi_{mit} + \theta_{bt} + \varepsilon_{it}, & \text{for } i = 1 \\ \psi_{mit} + \zeta_{it} + \epsilon_{it}, & \text{for } i > 1 \end{cases} \tag{62} \]

and

\[
\psi_{mit} = \begin{cases} -\sum_{\ell=m+1}^{\infty} a_{\ell} x_{1,t-\ell}, & \text{for } i = 1 \\ \sum_{\ell=m+1}^{\infty} \beta_{i\ell} x_{1,t-\ell}, & \text{for } i > 1 \end{cases} \tag{63} \]

Note that there are \( m \) regressors (and \( m \) unknown coefficients) in the regression for the dominant unit \( i = 1 \), and \( m + 2 \) regressors in the regressions for the non-dominant units, \( i > 1 \).

The error term \( \epsilon_{it} \) in (62) is decomposed into three parts: the component \( \psi_{mit} \) is due to the
truncation of the infinite order lag polynomials $a(L)$ in the case of the dominant unit and $\beta_i(L)$, for $i > 1$. Since the coefficients in these polynomials are absolutely summable, we have

$$\psi_{m^q} \xrightarrow{m \to \infty} 0,$$

for any $N \in \mathbb{N}$, any $i \in \{1, 2, ..., N\}$ and any $t \in \{1, 2, ..., T\}$. The second terms, $\vartheta_{it}$ (in the case of the dominant unit), and $\zeta_{it}$, for $i > 1$, are $O_p\left(N^{-1/2}\right)$ (See (38) and (55)). These terms arise from aggregation of weak dependencies in the individual-specific equations of the IVAR model, (1). The third terms in (62) are serially uncorrelated errors, with $\varepsilon_{1t}$ being orthogonal to $e_{it}$ for any $i > 1$. Also as noted above $e_{it}$ are cross sectionally weakly dependent, although ignoring such dependencies does not adversely impact the consistency of the estimators to be proposed here.

For future references, let

$$h_{it} = \begin{cases} 
(\xi_{1,t-1}, \xi_{1,t-2}, ..., \xi_{1,t-m}) & \text{for } i = 1 \\
(\xi_{i,t-1}, \xi_{1t}, \xi_{1,t-1}, ..., \xi_{1,t-m}) & \text{for } i > 1
\end{cases},$$

and

$$C_i = E(h_{it}h_{it}') ,$$

where

$$a(L) \xi_{1t} = \varepsilon_{1t},$$

and

$$(1 - \phi_{ii}L) \xi_{it} = \beta_i(L) \xi_{1t} + e_{it}, \text{ for } i = 2, 3, ..., N.$$

Process $\{\xi_{it}\}$ is large $N$ counterpart of $\{x_{it}\}$ in the following sense,

$$x_{it} - \xi_{it} = O_p\left(\sqrt{N}\right), \text{ for any } i \in \mathbb{N}.$$

Note that for any $i$, $\xi_{it}$ is a linear stationary process with absolute summable autocovariances.

### 4.2 Consistency of the Augmented Least Squares Estimator

In what follows we focus on the estimation of the parameters of the non-dominant units, $i > 1$. The results for the dominant unit can be derived in a similar way and are not included to save space. We denote the least squares estimator of the vector of unknown coefficients $\pi_i$ as

$$\hat{\pi}_i = \begin{pmatrix} \hat{a}_1 \\
\hat{a}_2 \\
\vdots \\
\hat{a}_m 
\end{pmatrix} \text{ and } \hat{\pi}_i \in \begin{pmatrix} \hat{\phi}_{ii} \\
\hat{\beta}_{i0} \\
\vdots \\
\hat{\beta}_{im} 
\end{pmatrix}, \text{ for } i > 1,$$

where $\hat{\phi}_{ii}$ refers to the augmented least squares (ALS) estimator of the own lag coefficient $\phi_{ii}$, $\hat{\beta}_{il}$, $l = 0, 1, 2, ..., m$, denote the estimators of the first $m + 1$ coefficients in $\beta_i(L)$, and $\hat{a}_l$ for
\( \ell = 1, 2, ..., m \) denote the estimators of the corresponding coefficients in \( a(L) \).

Note that the first two coefficients in \( \beta_i(L) \), as defined by (49), are (for \( i = 2, 3, ..., N \))

\[ \beta_{i0} = r_{i1}, \quad (69) \]

and

\[ \beta_{i1} = \phi_{i1} + r_{i1}a_1 + k_{i0}a_0 = \phi_{i1} - r_{i1} (\phi'_{-1}r_1 + \phi_{11}) + \phi'_{-1,i}r_1, \quad (70) \]

where \( k_{i0} = \phi'_{-1,i}r_1 \). See \( k_i(L) \) defined by (47). Also using \( c(L) \) and \( b_1(L) \) given by (29) and (28), respectively, we have,

\[ c_0 = 1, c_1 = -\phi_{11}, \text{ and } b_{10} = 1, b_{11} = \phi'_{-1}r_1. \]

Hence, (using \( c(L) \) in (35)) we have

\[ a_0 = 1, a_1 = -\phi_{11} - \phi'_{-1}r_1. \quad (71) \]

The higher order lag coefficients, \( \beta_{i\ell} \) and \( a_{\ell} \) for \( \ell = 2, 3, ..., \) in general depend on all elements of \( \Phi \) and \( r_1 \) and can be obtained similarly.

Result (69) shows that the contemporaneous effects of the dominant unit on the rest of the units, \( r_{i1} \), for \( i > 1 \), can be identified from \( \beta_{i0} \) and consistently estimated by \( \hat{\beta}_{i0} \). The own-lag effects of the non-dominant units, \( \phi_{ii} \) (for \( i > 1 \)), can also be consistently estimated using the unit-specific ALS regressions in (59). But due to the feedback effects from non-dominant units, the own-lag effect of the dominant unit, \( \phi_{11} \), cannot be identified from \( a_1 \). Using (71) we have \( \phi_{11} = -a_1 + \phi'_{-1}r_1 \), where \( \phi'_{-1}r_1 = \sum_{i=2}^{N} \phi_{1i}r_{1i}, \max_{i>1} \left| \phi_{1i} \right| < KN^{-1}, \text{ and } r_{1i}, i > 1 \), are coefficients that do not vary with \( N \). Hence \( \phi'_{-1}r_1 \) is \( O(1) \) and does not vanish as \( N \to \infty \). Using the estimates from the regressions for the non-dominant units we are able to identify \( r_{11} \). But due to the negligible lagged effects from the non-dominant units on the dominant unit, the parameters \( \phi_{1i} \), for \( i > 1 \) can not be identified when \( N \to \infty \). As a result a consistent estimate of \( \sum_{i=2}^{N} \phi_{1i}r_{1i} \) can not be obtained. Consequently, \( \phi_{11} \) is not identified when \( N \to \infty \). Accordingly, in the Monte Carlo experiments below, we shall only consider the finite sample properties of \( \hat{\beta}_{i0} \) and \( \hat{\phi}_{ii} \).

It is convenient to re-write (59) for \( t = m + 1, m + 2, ..., T \) in a matrix form as

\[ x_i = G_i \pi_i + \epsilon_i, \text{ for } i > 1, \quad (72) \]

where

\[ G_i \quad \text{(T-m)X(m+2)} = \begin{pmatrix} g'_{i,m+1} \\ g'_{i,m+2} \\ \vdots \\ g'_{i,T} \end{pmatrix}, \quad x_i \quad \text{X(T-m)X1} = \begin{pmatrix} x_{i,m+1} \\ x_{i,m+2} \\ \vdots \\ x_{i,T} \end{pmatrix}, \quad \text{and} \quad \epsilon_i \quad \text{X(T-m)X1} = \begin{pmatrix} \epsilon_{i,m+1} \\ \epsilon_{i,m+2} \\ \vdots \\ \epsilon_{i,T} \end{pmatrix}. \quad (73) \]
Hence,
\[
\hat{\pi}_i = (G'_i G_i)^{-1} G_i x_i. \quad (74)
\]

In the general case where \( \beta_i (L) \) is not a finite order polynomial the truncation lag \( m \) has to be selected depending on the available time series data, \( T \), so that omission of the higher order lags of \( x_{1t} \) is asymptotically negligible. We use subscript \( T \) to denote this explicit dependence of the truncation lag on the available time series data in the remainder of this paper, namely we set \( m_T = m (T) \), and consider the following types of convergence for \( N, T \) and \( m_T \).

**ASSUMPTION B1** \( m_T^2 / T \to \xi_1 \), where \( 0 < \xi_1 < \infty \), as \( T \to \infty \).

**ASSUMPTION B2** \( (N, T) \overset{\mathcal{D}}{\to} \infty \) at any order.

**ASSUMPTION B3** \( (N, T) \overset{\mathcal{D}}{\to} \infty \), and \( T/N \to \xi_2 \), where \( 0 < \xi_2 < \infty \).

**Remark 2** Assumption B1 presents a sufficient condition on the truncation lag \( m_T \) under which \( \hat{\pi}_i \) is consistent and asymptotically normal. Assumption B1 can also be replaced by the following two conditions:

\[
m_T^2 / T \to 0, \quad (75)
\]

and

\[
\lim_{T \to \infty} \rho^{m_T} \sqrt{T} = 0 \text{ for any } 0 < \rho < 1. \quad (76)
\]

Condition (76) ensures that \( m_T \) increase sufficiently rapidly so that the omitted variable problem from truncation of higher order lags is asymptotically negligible. Condition (75) ensures a sufficient degree of freedom to reliably estimate individual coefficients. Under Assumption B1 both of the above two conditions will be satisfied.

Identification of \( \pi_i \) requires invertibility of \( G'_i G_i \), which is postulated in the following assumption.

**ASSUMPTION 5** There exist integers \( T_0 \in \mathbb{N} \) and \( N_0 \in \mathbb{N} \) such that for all \( T \geq T_0 \), and \( N \geq N_0 \), matrix \( G'_i G_i \) is invertible.

Let
\[
\hat{C}_i = \frac{1}{T} G'_i G_i. \quad (77)
\]

Substitute (72) in (74) to obtain

\[
\sqrt{T} (\hat{\pi}_i - \pi_i) = \hat{C}_i^{-1} \frac{G'_i e_i}{\sqrt{T}},
\]

\[
= \left( \hat{C}_i^{-1} - C_i^{-1} \right) \frac{G'_i e_i}{\sqrt{T}} + C_i^{-1} \frac{G'_i e_i}{\sqrt{T}}
\]

\[
= \left( \hat{C}_i^{-1} - C_i^{-1} \right) \frac{G'_i e_i}{\sqrt{T}} + C_i^{-1} \frac{G'_i e_i}{\sqrt{T}}
\]

\[
= \left( \hat{C}_i^{-1} - C_i^{-1} \right) \frac{G'_i e_i}{\sqrt{T}} + C_i^{-1} \left[ \frac{(G_i - H_i)' e_i}{\sqrt{T}} + \frac{H_i' e_i}{\sqrt{T}} + \frac{G'_i \zeta_i}{\sqrt{T}} + \frac{G'_i \psi_i}{\sqrt{T}} \right], \text{ for } i > 1, \quad (78)
\]
where
\[
\mathbf{H}_i = \begin{pmatrix}
\mathbf{h}_{i,mT+1} \\
\mathbf{h}_{i,mT+2} \\
\vdots \\
\mathbf{h}_{iT}
\end{pmatrix},
\] (79)
and
\[
\mathbf{e}_i = \begin{pmatrix}
\epsilon_{i,mT+1} \\
\epsilon_{i,mT+2} \\
\vdots \\
\epsilon_{iT}
\end{pmatrix},
\mathbf{\zeta}_i = \begin{pmatrix}
\zeta_{i,mT+1} \\
\zeta_{i,mT+2} \\
\vdots \\
\zeta_{iT}
\end{pmatrix},
\mathbf{\psi}_i = \begin{pmatrix}
\psi_{mT,i,mT+1} \\
\psi_{mT,i,mT+2} \\
\vdots \\
\psi_{mTiT}
\end{pmatrix}.
\] (80)

Note that \( \epsilon_i = \epsilon_i + \zeta_i + \psi_i \), for \( i > 1 \), see (62).

We deal with the estimation of infinite order lag polynomials in a similar way as in Said and Dickey (1984) or Berk (1974). The following lemmas are needed to establish the consistency of \( \hat{\pi}_i \). Lemmas 4-6 are required for dealing with infinite lag orders, and Lemmas 7 and 8 are needed for averaging out the effects of weak dependencies (after conditioning on current and lagged values of the dominant unit) in the IVAR model (1).

**Lemma 4** Suppose \( \mathbf{x}_t \) is given by model (1) and Assumptions 1-4, B1, and B2 hold. Then for any \( i > 1 \) we have,
\[
\left\| \hat{\mathbf{C}}_i - \mathbf{C}_i \right\|_\infty \xrightarrow{P} 0,
\]
where \( \mathbf{C}_i \) and \( \hat{\mathbf{C}}_i \) are defined by (65) and (77), respectively.

**Proof.**
\[
\left\| \hat{\mathbf{C}}_i - \mathbf{C}_i \right\|_\infty = \max_{j \in \{1, \ldots, mT+2\}} \sum_{\ell=1}^{mT+2} \left| \hat{c}_{ij\ell} - c_{ij\ell} \right|,
\] (81)
where \( c_{ij\ell} \) and \( \hat{c}_{ij\ell} \) denote the \((j, \ell)\)th elements of \( \mathbf{C}_i \) and \( \hat{\mathbf{C}}_i \), respectively. Liapunov’s inequality and Lemma A.3 in Appendix establish
\[
E |\hat{c}_{ij\ell} - c_{ij\ell}| \leq \sqrt{E \left[ |\hat{c}_{ij\ell} - c_{ij\ell}|^2 \right]} \leq K \frac{1}{\sqrt{T}},
\] (82)
where \( K < \infty \) does not depend on \( N, m_T \in \mathbb{N} \), and \( j, \ell \in \{1, 2, \ldots, m_T + 2\} \). Taking expectations of both sides of (81) and making use of (82) yields
\[
E \left\| \hat{\mathbf{C}}_i - \mathbf{C}_i \right\|_\infty \leq K \frac{m_T + 2}{\sqrt{T}}.
\]
But under Assumption B1, \( m_T^2 / T \to 0 \), and hence \( \left\| \hat{\mathbf{C}}_i - \mathbf{C}_i \right\|_\infty \xrightarrow{L_1} 0 \). Convergence in \( L_1 \) norm implies convergence in probability. \( \blacksquare \)
Lemma 5 Suppose $x_t$ is given by model (1) and Assumptions 1-5, B1 and B2 hold. Then for any $i > 1$ we have,

$$\|\hat{C}_i^{-1} - C_i^{-1}\|_{\infty} \overset{p}{\to} 0,$$

where $C_i$ and $\hat{C}_i$ are defined by (65) and (77), respectively.

Proof. Let $p_c = \|C_i^{-1}\|_{\infty}$, $q_c = \|\hat{C}_i^{-1} - C_i^{-1}\|_{\infty}$, and $r_c = \|\hat{C}_i - C_i\|_{\infty}$. Using triangle inequality and submultiplicative property of matrix norm $\|\cdot\|_{\infty}$, we have

$$q_c = \|\hat{C}_i^{-1}(C_i - \hat{C}_i)C_i^{-1}\|_{\infty},$$

$$\leq \|\hat{C}_i^{-1}\|_{\infty}r_cp_c,$$

$$\leq \|\hat{C}_i^{-1} - C_i^{-1}\|_{\infty}r_cp_c,$$

and (subtracting $r_cp_cq_c$ from both sides)

$$\begin{align*}
(1 - r_cp_c)q_c & \leq p^2r_c.
\end{align*}$$

(83)

Note that $r_c \overset{p}{\to} 0$ by Lemma 4, and $p_c = O(1)$ since $\xi_{it}$, for $i \in \{1, 2, ..., N\}$, is a stationary invertible process with absolute summable autocovariances. Therefore

$$\begin{align*}
(1 - r_cp_c) & \overset{p}{\to} 1,
\end{align*}$$

(84)

and

$$p^2r_c \overset{p}{\to} 0.$$  

(85)

Results (83)-(85) imply that $q_c \overset{p}{\to} 0$, as desired.  

Lemma 6 Suppose $x_t$ is given by model (1) and Assumptions 1-4, B1 and B2 hold. Then for any $i > 1$ we have,

$$\left\| \frac{G_i'\psi_i}{\sqrt{T}} \right\|_{\infty} \overset{p}{\to} 0,$$

where $\psi_i$ is defined by (80), and $G_i$ is defined by (73).

Proof. Each of the individual elements of $G_i'\psi_i/\sqrt{T}$ can be expressed as

$$\frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} x_{j,t-s}\psi_{m_T},$$

Here we have used the fact that for any real constant $0 < \epsilon < 1$, the probability of $r_c p_c > \epsilon$ can be made arbitrarily small by choosing $T$ sufficiently large, since $r_c p_c \overset{p}{\to} 0$.  

18
for a suitable choice of $j \in \{1, i\}$, and $s \in \{0, 1, 2, \ldots, m_T\}$, where $\psi_{m_T}^{it}$ is defined by (63). We have

$$
E \left| \frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} x_{j,t-s} \psi_{it} \right| \leq \frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} E |x_{j,t-s} \psi_{it}| \\
\leq \frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} \left[ E (x_{j,t-s})^2 E (\psi_{it})^2 \right]^{1/2} \\
\leq \frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} \max_{j \in \{1, 2, \ldots, N\}} \left[ E (x_{j,t-s}^2) \right]^{1/2} \sum_{\ell=m_T+1}^{\infty} |\beta_{\ell t}| \left[ E (x_{1,t-\ell}^2) \right]^{1/2} (86)
$$

where the second inequality follows from the Cauchy-Schwarz inequality and the third inequality uses the triangle inequality, which implies $\|\psi_{it}\|_{L^2} \leq \sum_{\ell=m_T+1}^{\infty} |\beta_{\ell t}| \|x_{1,t-\ell}\|_{L^2}$. But by Lemma A.2

$$
\max_{j \in \{1, 2, \ldots, N\}} E \left( x_{jt}^2 \right) < K, \quad \text{and} \quad (86) \quad \text{now yields}
$$

$$
E \left| \frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} x_{j,t-s} \psi_{it} \right| \leq K \sqrt{T} \sum_{\ell=m_T+1}^{\infty} |\beta_{\ell t}| .
$$

But using Lemma 3 (for $0 < \rho < 1$)

$$
\sqrt{T} \sum_{\ell=m_T+1}^{\infty} |\beta_{\ell t}| \leq K \frac{\sqrt{T} p^{m_T+1}}{1 - \rho},
$$

and under Assumptions B1-B2, and noting that $K < \infty$ does not depend on $N$, or $T$, we have

$$
\sqrt{T} \sum_{\ell=m_T+1}^{\infty} |\beta_{\ell t}| \rightarrow 0, \quad \text{as} \quad T \rightarrow \infty,
$$

and hence

$$
\left\| \frac{G^i \psi_{\ell T}}{\sqrt{T}} \right\|_{L^1} \rightarrow 0.
$$

Convergence in $L^1$ norm implies convergence in probability. □

**Lemma 7** Suppose $x_t$ is generated according to (1) and Assumptions 1-4, B1 and B3 hold. Then for any $i > 1$,

$$
\left\| \frac{G_i^i \zeta_{\ell T}}{\sqrt{T}} \right\|_{\infty} \rightarrow 0, \quad (87)
$$

where matrix $G_i$ is defined by equation (73), and $\zeta_{\ell t}$ is defined by equation (80). Consider now the case where Assumption B2 is replaced by the weaker Assumption B2, but the other assumptions are maintained. Then for any $i > 1$,

$$
\left\| \frac{G_i^i \zeta_{\ell T}}{T} \right\|_{\infty} \rightarrow 0. \quad (88)
$$
Proof. The first element of the \((m_T + 2) \times 1\) dimensional vector \(G'_{\iota_i}/\sqrt{T}\) is

\[
\frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} x_{i,t-1} \zeta_{it}. \tag{89}
\]

Multiplying equation (27) by \(c^{-1}(L)\) and substituting the outcome into equation (24) for \(x_{1,t-1}\) yields the following relation for the non-dominant unit.

\[
x_{it} = f_i(L) \varepsilon_{1t} + d_i(L) c^{-1}(L) v_{1,t-1} + v_{it}, \text{ for } i > 1, \tag{90}
\]

where

\[
f_i(L) = Ld_i(L) c^{-1}(L) b_1(L) + b_i(L). \tag{91}
\]

The process \(\zeta_{it}\) as defined in (50) can be written as,

\[
\zeta_{it} = \phi'_{-1,-i} \nu_{t-1} - g_i(L) v_{1t}, \tag{92}
\]

where

\[
g_i(L) = [r_{i1} + k_i(L) L] b_1^{-1}(L). \tag{93}
\]

Coefficients in the polynomials \(c^{-1}(L), b_1(L), \text{ and } b_1^{-1}(L)\) are absolute summable (see Lemma 2). (58) implies absolute summability of the coefficients in \(k_i(L)\), and using the same arguments as in proof of Lemma 3, we have

\[
|d_{it}| = \left\| s'_{\ell} \Phi_{-1}\phi_1 \right\|_{\infty} < K \rho^\ell, \text{ and } b_{it} = \left\| s'_{\ell} \Phi_{-1} \nu_1 \right\|_{\infty} < K \rho^\ell. \tag{94}
\]

It follows that polynomials \(f_i(L), d_i(L) c^{-1}(L), \text{ and } g_i(L)\) in (90) and (92) are absolute summable. Vector \(\phi_{-1,-i}\) satisfies \(\| \phi_{-1,-i} \|_{\infty} = O(N^{-1})\) by condition (6) of Assumption 1 and result (A.26) of Lemma A.5 in Appendix imply (for \(\theta = \phi'_{-1,-i}, \text{ and } p = q = 1\))

\[
\frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} \varepsilon_{1,t-1} \phi'_{-1,-i} \nu_{t-1} \overset{L_1}{\longrightarrow} 0. \tag{95}
\]

Result (A.27) of Lemma A.5 imply (by setting \(p = 1, \text{ and } q = 0\))

\[
\frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} \varepsilon_{1,t-1} v_{1t} \overset{L_1}{\longrightarrow} 0. \tag{96}
\]

Noting again that \(\| \phi_{-1,-i} \|_{\infty} = O(N^{-1})\), result (A.46) of Lemma A.6 imply (for \(i = 1, p = 2, \text{ and } \theta = \phi_{-1,-i}\))

\[
E \left( v_{1,t-2} \phi'_{-1,-i} \nu_{t-1} \right) = O(N^{-1}). \tag{97}
\]
(97) and result (A.24) of Lemma A.5 in Appendix yields (for $\eta = s_1, \theta = \phi'_{-1,-i}, p = 1, \text{and } q = 2$)

$$\frac{1}{\sqrt{T}} \sum_{t = m_T + 1}^{T} v_{1,t-2} \phi'_{-1,-i} \nu_{t-1} \mathop{\xrightarrow{L_1}} 0.$$ \hfill (98)

Result (A.47) of Lemma A.6 yields (for $p = 2$ and $i = 1$)

$$E(v_{1,t-2}v_{1t}) = O\left(N^{-1}\right).$$ \hfill (99)

(99) and result (A.25) of Lemma A.5 in Appendix imply (for $\eta = s_1, p = 0 \text{ and } q = 2$)

$$\frac{1}{\sqrt{T}} \sum_{t = m_T + 1}^{T} v_{1,t-2}v_{1t} \mathop{\xrightarrow{L_1}} 0.$$ \hfill (100)

Similarly to (98) and (100), results (A.24) and (A.25) of Lemma A.5 in Appendix can be used (for a suitable choice of $\eta, \theta, p \text{ and } q$) to show that

$$\frac{1}{\sqrt{T}} \sum_{t = m_T + 1}^{T} v_{i,t-1} \phi'_{-1,-i} \nu_{t-1} \mathop{\xrightarrow{L_1}} 0,$$ \hfill (101)

and

$$\frac{1}{\sqrt{T}} \sum_{t = m_T + 1}^{T} v_{i,t-1}v_{1t} \mathop{\xrightarrow{L_1}} 0,$$ \hfill (102)

where we have also used Lemma A.6 (for a suitable choice of $p, i \text{ and } \theta$), which implies

$$E(v_{i,t-1} \phi'_{-1,-i} \nu_{t-1}) = O\left(N^{-1}\right),$$ \hfill (103)

and

$$E(v_{i,t-1}v_{1t}) = O\left(N^{-1}\right).$$ \hfill (104)

Substituting equation (90) for $x_{i,t-1}$ and definition of $\zeta_{it}$ (see (92)) in (89), and using results (95), (96), (98), (100), (101) and (102) establish

$$E\left(\frac{1}{\sqrt{T}} \sum_{t = m_T + 1}^{T} x_{i,t-1} \zeta_{it}\right) \rightarrow 0,$$ \hfill (105)

where we have used the fact that the coefficients of the polynomials $f_i(L), d_i(L) c^{-1}(L), \text{and } g_i(L)$ are absolute summable. Similarly to proof of result (105), Lemma A.5 in Appendix can be used repeatedly for a suitable choice of $p, q, \eta \text{ and } \theta$ to show that

$$\max_{p \in \{0,1,2,\ldots,m_T\}} E\left(\frac{1}{\sqrt{T}} \sum_{t = m_T + 1}^{T} x_{1,t-p} \zeta_{it}\right) \rightarrow 0,$$ \hfill (106)
where $x_{1t}$ is given by (40). Results (105), (106) complete the proof of (87) by noting that convergence in $L_1$ norm implies convergence in probability. Proof of result (88) can be constructed in the same way, but this time Lemma A.4 is used instead of Lemma A.5 and the expansion rates considered for $N$ and $T$ under Assumptions B1 and B2.

Lemma 8  Suppose $x_t$ is generated according to (1), and Assumptions 1-4, B1 and B3 hold. Then for any $i > 1$,

$$\frac{\| (G_i - H_i)' e_t \|}{\sqrt{T}} \rightarrow^p 0,$$  \hspace{1cm} (107)

where $G_i$ and $H_i$ are defined by (73), and (79), respectively. Consider now the case where Assumption B3 is replaced by the weaker Assumption B2, but the other assumptions are maintained. Then for any $i > 1$,

$$\frac{\| (G_i - H_i)' e_t \|}{T} \rightarrow^p 0.$$  \hspace{1cm} (108)

Proof. Since $|\phi_{it}| < 1$ by condition (16) of Assumption 4, polynomial $(1 - \phi_{it} L)^{-1}$ exists (for any $i = 2, 3, ..., N$). Multiplying equation (A.8) in Appendix by $(1 - \phi_{it} L)^{-1}$ yields

$$x_{it} - \xi_{it} = (1 - \phi_{it} L)^{-1} [\beta_i (L) \sigma + \zeta_{it}], \text{ for } i = 2, 3, ..., N,$$  \hspace{1cm} (109)

where $\zeta_{it}$ is given by (92). Under Assumptions B1 and B3, and using (109) and Lemma A.5 in Appendix (results (A.28) and (A.29)), it can be shown that (for a suitable choice of $p$, $q$ and vector $\theta$, similarly as in proof of Lemma 7), for any $i > 1$ we have

$$\max_{j \in \{1, i\}, \, p \in \{1, 2, ..., m_T\}} E \left| \frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} (x_{j,t-p} - \xi_{j,t-p}) e_{it} \right| \rightarrow 0,$$  \hspace{1cm} (110)

and

$$E \left| \frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} (x_{1t} - \xi_{1t}) e_{it} \right| \rightarrow 0.$$  \hspace{1cm} (111)

Noting that

$$g_{it} - h_{it} = \begin{cases} (x_{1,t-1} - \xi_{1,t-1}, x_{1,t-2} - \xi_{1,t-2}, ..., x_{1,m_T} - \xi_{1,m_T}) & \text{for } i = 1, \\ (x_{i,t-1} - \xi_{i,t-1}, x_{i,t} - \xi_{i,t}, x_{i,t-1} - \xi_{i,t-1}, ..., x_{i,m_T} - \xi_{i,m_T}) & \text{for } i > 1, \end{cases}$$

then (110)-(111) establish (107). Proof of (108) is identical, but this time Lemma A.4 is used instead of Lemma A.5, together with Assumptions B1 and B2.

Using Lemmas 4-8, it is now straightforward to establish consistency of $\pi_i$ in the following theorem.

Theorem 1  (Consistency) Suppose $x_t$ is given by model (1) and Assumptions 1-5, B1, and B2 hold. Then

$$\| \hat{\pi}_i - \pi_i \|_\infty \rightarrow^p 0, \text{ for any } i \in \mathbb{N},$$  \hspace{1cm} (112)
that is \( \hat{\pi}_i \) defined by equation (74) is a consistent estimator of \( \pi_i \).

**Proof.** Suppose \( i > 1 \). Taking maximum absolute row-sum matrix norms of both sides of equation (78), we have

\[
\| \pi_i - \pi_i \|_\infty \leq \left\| \left( \frac{G_iG_i}{T} \right)^{-1} - C_i^{-1} \right\|_\infty \left\| \frac{G_i'\varepsilon_i}{T} \right\|_\infty \\
+ \| C_i^{-1} \|_\infty \left( \left\| \frac{(G_i - H_i)'e_i}{T} \right\|_\infty + \left\| \frac{H_i'e_i}{T} \right\|_\infty + \left\| \frac{G_i'\xi_i}{T} \right\|_\infty + \left\| \frac{G_i'\psi_i}{T} \right\|_\infty \right),
\]

where \( \| C_i^{-1} \|_\infty = O(1) \) since \( \xi_{it} \) is a stationary invertible process with absolute summable autocovariances. The desired result (112), for \( i > 1 \), now follows using Lemmas 4-8 and noting that \( \| H_i'e_i/T \|_\infty \overset{p}{\to} 0 \) by results (A.15) and (A.16) of Lemma A.4 in Appendix. Consistency of \( \pi_1 \) can be established in a similar manner. ■

### 4.3 Asymptotic Distribution of \( \hat{\pi}_i \)

We continue to focus on the estimates \( \pi_i \) for \( i > 1 \). Derivation of the asymptotic results for \( \pi_1 \) can be established in a similar manner.

**Theorem 2** (Asymptotic normality) Suppose \( x_t \) is given by model (1) and Assumptions 1-5, B1, and B3 hold. Then for any sequence of \( (m_T + 2) \times 1 \) dimensional vectors \( a \) such that \( \| a \|_1 = O(1) \), we have

\[
\sqrt{T} \frac{1}{\sigma_i} a'C_i^1 (\pi_i - \pi_i) \xrightarrow{d} N(0, 1), \text{ for any } i \in \{2, 3, \ldots\},
\]

where \( \pi_i \) and \( C_i \) are defined by (74) and (65), respectively, and \( \sigma_i^2 = \text{Var}(e_{it}) \). In addition, for any sequence of \( m_T \times 1 \) dimensional vectors \( b \) such that \( \| b \|_1 = O(1) \), we have

\[
\sqrt{T} \frac{1}{\sigma_{\varepsilon_1}} b'C_1^1 (\pi_1 - \pi_1) \xrightarrow{d} N(0, 1),
\]

where \( \pi_1 \) and \( C_1 \) are defined by (74) and (65), respectively, and \( \sigma_{\varepsilon_1}^2 = \text{Var}(\varepsilon_{1t}) \).

**Proof.** Suppose \( i > 1 \).

\[
\left\| \sqrt{T} \frac{1}{\sigma_i} a'C_i^1 (\pi_i - \pi_i) - \frac{1}{\sigma_i} a'C_i^{-\frac{1}{2}} \frac{H_i'e_i}{\sqrt{T}} \right\|_\infty \leq \left\| \frac{1}{\sigma_i} a'C_i^\frac{1}{2} \right\|_\infty \\
\cdot \left\| \sqrt{T} (\pi_i - \pi_i) - C_i^{-\frac{1}{2}} \frac{H_i'e_i}{\sqrt{T}} \right\|_\infty,
\]

(115)
where $\frac{1}{\sigma_i} a' C_i^{\frac{1}{2}} \rightarrow 0$. Using (78) we have

$$\sqrt{T} (\pi_i - \pi_i) - C_i^{-1} H_i' e_i \leq \left( \frac{G_i' G_i}{T} \right)^{-1} - C_i^{-1} \frac{G_i' e_i}{\sqrt{T}} \leq \frac{G_i' e_i}{\sqrt{T}}$$

$$+ \frac{G_i' e_i}{\sqrt{T}} \left( \frac{G_i'H_i'e_i}{\sqrt{T}} + \frac{G_i' \psi e_i}{\sqrt{T}} \right)$$

$$\xrightarrow{p} 0, \quad \text{(116)}$$

where the convergence follows from Lemmas 4-8. Furthermore,

$$\frac{1}{\sigma_i} a' C_i^{\frac{1}{2}} \frac{H_i' e_i}{\sqrt{T}} \xrightarrow{d} N (0, 1) \quad \text{(117)}$$

is a standard time series result, which can be established using the martingale difference array central limit theorem (Theorem 24.3 of Davidson (1994)) in the same way as Lemma 6 of Chudik and Pesaran (2010). Equations (115)-(117) establish result (113), as desired. Asymptotic distribution of $\pi_1$ can be established in a similar manner.

4.4 Extensions

Straightforward relaxation of Assumption 1 would be to incorporate more general neighborhood effects with a priori known spatial weights matrix or a priori known selection matrix that selects neighbors for unit $i$. This extension is straightforward along the lines of CP and we provide below some Monte Carlo evidence in case of three neighbors per unit. The presence of deterministic terms or observed and unobserved common factors could also be tackled along the same lines as in CP. It is also possible to allow for more than one dominant unit in the IVAR model so long as the number of dominant units is fixed and the identity of the dominant units is known a priori.

5 Monte Carlo Experiments

In this section we report some evidence on the small sample properties of the augmented least squares estimator $\hat{\pi}_i$. The data generating process (DGP) is given by the following stationary IVAR featuring the dominant unit and augmented by an unobserved common factor.

$$(x_t - \gamma f_t) = \Phi (x_{t-1} - \gamma f_{t-1}) + u_t, \quad \text{(118)}$$

where

$$u_t = R \varepsilon_t = \nu_1 \varepsilon_{1t} + e_t, \quad \text{(119)}$$

which corresponds to model (1) augmented by unobserved common factor $f_t$ and residuals correspond to (8) and (20). Our focus is on estimation of the lagged own coefficient in equation for the
The focus parameters of the dominant unit depend on \( \gamma = 0 \).\(^7\) Corresponding ALS estimators for these coefficients are denoted by \( \hat{\phi}_{22}, \hat{\phi}_{23}, \) and \( \hat{\beta}_{20}, \) respectively.

The elements of \( \Phi \) are generated so that unit 1 is dominant, and there are non-zero neighborhood effects. To this end we first generate

\[
\omega_{ij} = \begin{cases} 
\frac{\varsigma_{ij}}{\sum_{j \notin \{1, i, i+1\}} \varsigma_{ij}}, & \text{for } j \notin \{1, i, i+1\} \\
0, & \text{for } j \in \{1, i, i+1\}
\end{cases}
\]

with \( \varsigma_{ij} \sim II DU (0, 1) \). This ensures that \( \omega_{ij} = O_p(N^{-1}) \), and \( \sum_{j=1}^{N} \omega_{ij} = 1 \). Individual elements of the matrix \( \Phi \) are then generated as follows:

1. (Dominant Unit \( i = 1 \)) \( \phi_{11} = 0.7 \), and \( \phi_{1j} = \lambda_{1} \omega_{1j} \) for \( j = 2, 3, \ldots, N \), with \( \lambda_{1} = 0.1 \).
2. (Unit \( i = 2 \)) \( \phi_{21} = 0.1, \phi_{22} = 0.5, \phi_{23} = 0.1, \) and \( \phi_{2j} = \lambda_{2} \omega_{2j} \) for \( j = 3, 4, \ldots, N \), with \( \lambda_{2} = 0.1 \).
3. (Remaining units \( i > 2 \)) \( \phi_{ii} \sim II DU (0.3, 0.5), \phi_{i1} \sim II DU (0, 0.1), \phi_{i,i+1} \sim II DU (-0.2, 0.2), \) and \( \phi_{ij} = \lambda_{i} \omega_{ij} \) for \( j \notin \{1, i, i+1\} \), where \( \lambda_{i} \sim II DU (-0.05, 0.15) \).

The focus parameters of the dominant unit 1, and unit \( i = 2 \) are fixed across all experiments. The remaining parameters are generated randomly. In all experiments \( \Phi \) is generated such that \( \| \Phi \|_{\infty} \leq 0.95 \), which is a sufficient condition for stationarity of the IVAR model.

Two sets of factor loadings are considered, \( \gamma = 0 \) (no unobserved common factor) and \( \gamma \neq 0 \). Under the latter we set \( \gamma_{1} = 1, \gamma_{2} = -0.5 \), and the remaining factor loadings are generated randomly as \( \gamma_{i} \sim 0.5 \phi_{ii} + II DN (1, 1) \) for \( i = 3, 4, \ldots, N \). The factor loadings are generated to depend on \( \phi_{ii} \), so that the robustness of the ALS estimator to this type of dependency can be evaluated. The common factor \( f_{t} \) is generated as

\[
f_{t} = \rho_{f} f_{t-1} + \varepsilon_{f t},
\]

where \( \varepsilon_{f t} \sim II DN \left(0, 1 - \rho_{f}^{2}\right) \), which yields \( Var (f_{t}) = 1 \). We choose relatively persistent common factor with \( \rho_{f} = 0.9 \). We set \( e_{t} = 0 \) and generate the remaining error terms \( \{e_{2t}, e_{3t}, \ldots, e_{Nt}\} \) from a stationary spatial process in order to show that our estimators are invariant to the weak cross section dependence of innovations. The following bilateral Spatial Autoregressive Model (SAR) is considered.

\[
e_{it} = \frac{\alpha_{r}}{2} (e_{i-1,t} + e_{i+1,t}) + \eta_{eit}, \quad (120)
\]

where \( \eta_{eit} \sim II DN \left(0, \sigma_{ne}^{2}\right) \). As established by Whittle (1954), the unilateral SAR(2) scheme

\[
e_{it} = \delta_{e1} e_{i-1,t} + \delta_{e2} e_{i-2,t} + \eta_{eit}, \quad (121)
\]

\(^7\) Similar results are also obtained for other cross section units.
with $\delta_{e1} = -2b_e$, $\delta_{e2} = b_e^2$ and $b_e = \left(1 - \sqrt{1 - \alpha_e^2}\right)/\alpha_e$, generates the same autocorrelations as the bilateral SAR(1) scheme (120). The error terms are generated using the unilateral scheme (121) with 50 burn-in data points ($i = -49, -48, \ldots, 0$), and the initializations $e_{-51} = e_{-50} = 0$. The spatial AR parameter, $a_e$, is set to 0.4, which ensures that the process $\{e_{it}\}$ is cross sectionally weakly dependent. $\sigma_{eit}^2 = \text{Var}(e_{it})$ is chosen so that the variance of errors $e_{it}$ is equal to 0.1. $\varepsilon_{it} \sim \text{IIDN}(0, 0.15)$ and $r_{11} = 1$, which implies that $\text{Var}(u_{1t}) = 0.15$. The second element of $r_1$ in (119) is set to $r_{21} = 0.1$ and the remaining elements are generated as $r_{i1} \sim \text{IIDU}(0, 0.2)$ for $i = 3, 4, \ldots, N$.

We consider three different types of augmentation. In addition to the lagged neighbor unit 3, the regression for unit $i = 2$ is augmented by the following set of regressors: (i) the current and lagged values of the dominant unit, $\{x_{1,t-\ell}\}_{\ell=0}^{m_T}$, (ii) the simple cross section averages $\{\bar{x}_{t-\ell}\}_{\ell=0}^{m_T}$, and (iii) $\{x_{1,t-\ell}, \bar{x}_{t-\ell}\}_{\ell=0}^{m_T}$. In all the three cases $m_T$ is set to the integer value of $T^{1/3}$, which we denote by $\lceil T^{1/3} \rceil$.\(^9\) For example, under case (i) the ALS regression for unit $i = 2$ is specified as:

$$x_{2t} = c_2 + \phi_{22}x_{2,t-1} + \phi_{23}x_{3,t-1} + \sum_{\ell=0}^{[T^{1/3}]} b_{1\ell}x_{1,t-\ell} + \varepsilon_{2t}.$$ \(\label{eq:122}\)

### 5.1 Monte Carlo results

We report results for experiments without the unobserved common factor first. Table 1 summarizes the results for the own coefficient $\phi_{22}$, and Table 2 summarizes the results for the neighbor coefficient, $\phi_{23}$. Each table gives the bias and the root mean squared error (RMSE) of the estimator as well as the empirical size and power of tests based on it. The results for $\hat{\phi}_{23}$ are a little better but overall similar to those for $\hat{\phi}_{22}$. The bias and RMSE of these estimators decline as $N$ and $T$ are increased irrespective of the augmentation procedure adopted. This is because in the absence of a common factor the dominant unit and the cross section averages are asymptotically equivalent and either set of variables (with long enough lags) are sufficient to deal with the cross section dependence and the omitted variable problems in the IVAR model. The augmentation by cross section averages has the advantage that it works regardless of whether strong cross section dependence is due to a dominant unit, or due to a different source such as an unobserved common factor. Full augmentation by the dominant unit as well as the cross section averages is not necessary in the absence of a common factor, and yields worse outcomes in terms of RMSEs. See the third panel of Tables 1 and 2.

The empirical size of the tests for values of $T > 50$ are also close to the 5 percent nominal level. For smaller values of $T$, however, there is a negative bias and the tests are oversized. This is the familiar time series bias where even in the absence of cross section dependence the LS estimators of autoregressive coefficients are biased in small $T$ samples. But the size of the tests does not change much with $N$, which is in line with the findings reported in CP. Overall, these findings suggest that $N$ need not to be very large for the ALS estimator to work.

\(^8\)The variance of errors $\{e_{it}\}$ is given by $\sigma^2 = (1 + \delta_{e2}) \left[(1 - \delta_{e2}^2) - \delta_{e1}^2\right]/(1 - \delta_{e2})$.

\(^9\) $m_T = 2, 3, 4, 5$ for $T = 25, 50, 75, 100, 200$, respectively.
Results for $\beta_{20}$ are reported in Table 3. The top panel summarizes the results when the regression is augmented with $\{x_{1,t-\ell}\}_{\ell=0}^{m_T}$, as suggested by the theory. In this case the bias and RMSE of $\beta_{20}$ declines with $N$ and $T$, and the empirical size is close to the nominal value of the test, very much in line with the results reported for $\hat{\phi}_{22}$ and $\hat{\phi}_{23}$. In contrast, the estimates at the bottom panel of Table 3 that are based on regressions augmented by $\{x_{1,t-\ell}, \bar{x}_{t-\ell}\}_{\ell=0}^{m_T}$, behave less well and for a given $T$ the RMSEs deteriorate as $N$ increases. The inclusion of cross section averages lead to a multicollinearity problem since $\{x_{1,t-\ell}\}_{\ell=0}^{m_T}$ and $\{\bar{x}_{t-\ell}\}_{\ell=0}^{m_T}$ will be asymptotically equivalent. But this asymptotic multicollinearity problem does not affect the estimation of $\phi_{22}$ and $\phi_{23}$.

Results for the experiments with the unobserved common factor are reported in Table 4 (own coefficient $\phi_{22}$) and Table 5 (neighbor coefficient $\phi_{23}$). Theory suggests that augmentation by the dominant unit or by the cross section averages alone is not enough for consistent estimation in the presence of a dominant unit as well as a common factor, $f_t$. This is confirmed by the MC results in Tables 4 and 5, which indeed show substantial biases and significant size distortions in cases without the full augmentation (the empirical sizes are in the range $17\% - 70\%$ for $N = T = 200$). The ALS estimator based on the full augmentation is correctly sized for larger values of $N$ and $T$ and overall its performance is very similar to the experiments without the unobserved common factor.

6 Concluding Remarks

This paper has extended the analysis of infinite dimensional vector autoregressive (IVAR) models by Chudik and Pesaran (2010) to the case where one variable or a cross section unit is dominant in the sense that it has non-negligible contemporaneous and/or lagged effects on all other units even as the cross section dimension rises without a bound. We showed that the asymptotic normality of the augmented least squares (ALS) estimator continues to hold once the individual auxiliary regressions are correctly specified. Satisfactory finite sample performance was documented by means of Monte Carlo experiments.

How to specify the individual regressions is an important topic, and the correct specification depends on a number of assumptions, namely the presence of dominant units, observed and unobserved common factors and spatiotemporal neighborhood effects. How to identify the dominant unit(s), the number of the unobserved common factors (if any), and the nature of (spatial) contemporaneous dependencies are issues of utmost importance that lie outside the scope of the present paper. These topics together with the extension of the analysis to nonstationary IVAR models must be left to future studies.

---

10 Results for $\beta_{20}$ are not reported in this case since only in the absence of common factor, coefficient $\beta_{20}$ corresponding to the contemporaneous value of the dominant unit equals $r_{21}$, as shown in equation (69).

Notes: $\phi_{22} = 0.5$, $\phi_{23} = 0.1$, and $\lceil T^{1/3} \rceil$ refers to the integer part of $T^{1/3}$, so that $m_T = 2, 3, 4, 5$ for $T = 25, 50, 75, 100, 200$ respectively. The DGP is defined by (118) where the equation for unit $i \in \{2, 3, \ldots, N-1\}$ is $x_{it} - \gamma_i f_t = \sum_{j=1}^{N} \phi_{ij} (x_{jt-1} - \gamma_j f_{t-1}) + \tau_{it} \varepsilon_{it} + \varepsilon_{it}$, unit 1 is dominant, the neighbor of unit $i$ are units $\{1, i, i+1\}$ for $i \in \{2, 3, \ldots, N-1\}$, and innovations $\{\varepsilon_{it}\}$ are generated from spatial autoregressive model (121) and $\varepsilon_{it} = 0$. The ALS estimator of the coefficient $\phi_{22}$ is computed using the auxiliary regression, $x_{2t} = c_2 + \phi_{22} x_{2,t-1} + \phi_{23} x_{3,t-1} + \sum_{\ell=1}^{m_T} a_{2\ell} \delta_{t-\ell} + \varepsilon_{2t}$, where three different augmentation schemes are considered for the vector $\delta_t$: cross section averages, dominant unit $i = 1$, or both. See Section 5 for a detailed description of the Monte Carlo design.

A Supplementary Lemmas and Proofs

Lemma A.1 Let $\psi(L) = \sum_{\ell=0}^{\infty} \psi_{\ell} L^\ell$, $\psi_0 = 1$ and there exists a real positive constant $0 < \rho < 1$ such that $|\psi_{\ell}| \leq \rho^\ell$ for any $\ell \in \mathbb{N}$. Then there exists polynomial $\theta(L) = \sum_{\ell=0}^{\infty} \theta_{\ell} L^\ell$ such that $\psi(L) \theta(L) = 1$,

$$|\theta_\ell| \leq \left(1 + \frac{\ell(\ell - 1)}{2}\right) \rho^\ell \quad \text{for any } \ell \in \mathbb{N}, \quad (A.1)$$

and there also exist real constants $K < \infty$, and $0 < \rho_1 < 1$ such that

$$|\theta_\ell| \leq K \rho_1^\ell \quad \text{for any } \ell \in \mathbb{N}. \quad (A.2)$$

Proof. We have

$$\theta_0 = 1, \quad \theta_1 = -\psi_1, \quad \theta_2 = -\psi_1 \theta_1 - \psi_2, \quad \theta_3 = -\psi_1 \theta_2 - \psi_2 \theta_1 - \psi_3, \quad \theta_4 = -\psi_1 \theta_3 - \psi_2 \theta_2 - \psi_3 \theta_1 - \psi_4.$$ 

Note that

$$\begin{align*}
|\theta_1| &= |\psi_1|, \\
|\theta_2| &\leq |\psi_1| |\theta_1| + |\psi_2|, \\
|\theta_3| &\leq |\psi_1| |\theta_2| + |\psi_2| |\theta_1| + |\psi_3|, \\
|\theta_4| &\leq |\psi_1| |\theta_3| + |\psi_2| |\theta_2| + |\psi_3| |\theta_1| + |\psi_4|,
\end{align*}$$

and by recursive substitution

$$\begin{align*}
|\theta_1| &= |\psi_1|, \\
|\theta_2| &\leq |\psi_1| |\theta_1| + |\psi_2| = |\psi_1|^2 + |\psi_2|, \\
|\theta_3| &\leq |\psi_1| |\theta_2| + |\psi_2| |\theta_1| + |\psi_3| \leq |\psi_1| |\psi_1|^2 + |\psi_2| + |\psi_1| + |\psi_3|, \\
|\theta_4| &\leq |\psi_1|^3 + 2 |\psi_2| |\psi_1| + |\psi_3|, \\
|\theta_5| &\leq |\psi_1|^4 + 3 |\psi_1|^2 |\psi_2| + 2 |\psi_1| |\psi_3| + |\psi_2|^2 + |\psi_4|.
\end{align*}$$

Suppose that $|\psi_1| \leq \rho^1$ and $0 < \rho < 1$. Then in general

$$\begin{align*}
|\theta_s| &\leq \left(1 + \sum_{j=1}^{s-1} j\right) \rho^s, \\
|\theta_s| &\leq \left(1 + \frac{s(s-1)}{2}\right) \rho^s,
\end{align*}$$

Choose a positive real constant $\epsilon > 0$ such that $\rho < 1 - \epsilon$. We have

$$\begin{align*}
|\theta_s| &\leq \left(1 + \frac{s(s-1)}{2}\right) (1 - \epsilon)^s \left(\frac{\rho}{1 - \epsilon}\right)^s, \\
|\theta_s| &\leq \left[1 + \frac{s(s-1)}{2}\right] \rho_2^s \rho_1^s,
\end{align*}$$

where $\rho_1 \equiv \rho/(1 - \epsilon)$, $\rho_2 \equiv 1 - \epsilon$, and note that $0 < \rho_1 < 1$, $0 < \rho_2 < 1$. Also,

$$\left(1 + \frac{s(s-1)}{2}\right) \rho_2^s \to 0, \text{ as } s \to \infty,$$
which implies existence of a real constant $K < \infty$ such that

$$
\left(1 + \frac{s(s-1)}{2}\right) \rho_s^2 < K.
$$

It follows that $|\theta_s| < K \rho_s^2$, as desired. ■

**Lemma A.2** Suppose $x_t$ is generated according to (1), and Assumptions 1-4, B1, and B2 hold. Then

$$
\max_{1 \leq i \leq N} E \left( x_{it}^2 \right) < K, \quad (A.3)
$$

for any $N \in \mathbb{N}$, and any $t \in \mathbb{Z}$, where constant $K$ does not depend on $N$.

**Proof.** Taking $L_2$-norm of (40) and using triangle inequality, we obtain

$$
\|x_{1t}\|_{L_2} = \|\xi_{1t} + \theta_{ct}\|_{L_2} \leq \|\xi_{1t}\|_{L_2} + \|\theta_{ct}\|_{L_2}, \quad (A.4)
$$

where $\xi_{1t} = a^{-1}(L) \varepsilon_{1t}$ (see (66)). Noting that $E(\theta_{ct}) = 0$, (41) implies

$$
\|\theta_{ct}\|_{L_2} = O\left(N^{-1/2}\right). \quad (A.5)
$$

Since coefficients of $a^{-1}(L) = c^{-1}(L) b_1(L)$ are absolute summable (see Lemma 2), $E(\varepsilon_{1t}) = 0$, and $\sigma^2_{z_t} = Var(\varepsilon_{1t})$ is bounded under Assumption 2 (condition (10)), we have

$$
\|\xi_{1t}\|_{L_2} < K. \quad (A.6)
$$

Using (A.5) and (A.6) in (A.4), we obtain

$$
E \left( x_{1t}^2 \right) = \|x_{1t}\|_{L_2}^2 < K < \infty, \quad (A.7)
$$

where $K$ does not depend on $N$.

Now suppose $i > 1$. Subtracting (67) from (48) yields

$$
(1 - \phi_{ii} L) x_{it} = (1 - \phi_{ii} L) \xi_{it} + \beta_i(L) \theta_{ct} + \zeta_{it}, \quad (A.8)
$$

where $\theta_{ct} = x_{1t} - \xi_{1t}$ (see (40) and (66)), and $\zeta_{it}$ is given by (50). $|\phi_{ii}| \leq \rho < 1$ by condition (16) of Assumption 4, and therefore polynomial $(1 - \phi_{ii} L)$ is invertible for any $i \in \{2, 3, \ldots\}$. Multiplying (A.8) by $(1 - \phi_{ii} L)^{-1}$, taking $L_2$ norm and using triangle inequality yields

$$
\|x_{it}\|_{L_2} \leq \|\xi_{it}\|_{L_2} + \left\| (1 - \phi_{ii} L)^{-1} \beta_i(L) \theta_{ct} \right\|_{L_2} + \left\| (1 - \phi_{ii} L)^{-1} \zeta_{it} \right\|_{L_2}.
$$

But coefficients of $(1 - \phi_{ii} L)^{-1}$ and $\beta_i(L)$ are absolute summable, see Lemma 3. Using (41) and (54), noting that $E(\theta_{ct}) = 0$, and$^{11}$

$$
\|\xi_{it}\|_{L_2} < K, \text{ for any } N \in \mathbb{N}, \text{ and any } i \in \{2, 3, \ldots, N\} , \quad (A.9)
$$

$$
\left\| (1 - \phi_{ii} L)^{-1} \beta_i(L) \theta_{ct} \right\|_{L_2} = O\left(N^{-1/2}\right), \text{ and } \left\| (1 - \phi_{ii} L)^{-1} \zeta_{it} \right\|_{L_2} = O\left(N^{-1/2}\right),
$$

we obtain

$$
E \left( x_{it}^2 \right) = \|x_{it}\|_{L_2}^2 < K \text{ for any } N \in \mathbb{N} \text{ and any } i \in \{2, 3, \ldots, N\}. \quad (A.10)
$$

Results (A.8) and (A.10) establish (A.3), as desired. ■

$^{11}$ Result (A.9) follows from definition of stationary process $\xi_{it}$ (given by (67)) by noting that $Var(\varepsilon_{it})$ is bounded under Assumption 2 (conditions (10) and (11)), coefficients in polynomial $\beta_i(L)$ are absolute summable (see Lemma 3) and that (A.6) holds.
Lemma A.3 Suppose \( \mathbf{x}_t \) is generated according to (1), and Assumptions 1-4, B1, and B2 hold. Then there exists a constant \( K < \infty \), which does not dependent on \( N, m_T \in \mathbb{N}, i, j \in \{1, 2, \ldots, N\}, \) and \( s \in \{1, 2, \ldots, m_T\} \), such that

\[
E \left( \frac{1}{T} \sum_{t=m_T+1}^{T} x_{t,t-\tau} - E (\xi_{it} \xi_{j,t-\tau}) \right)^2 \leq \frac{K}{T}, \tag{A.11}
\]

where \( \xi_{it} \) for \( i \in \{2, 3, \ldots\} \), is defined by equation (67) and \( \xi_{it} \) is defined by (66).

Proof. (A.11) can be established in a similar way to the proof of equations (2.10) and (2.11) in Berk (1974).

Lemma A.4 Suppose Assumptions 1-4, B1, and B2 hold. Then for any \( p, q \in \{0, 1, 2, \ldots\} \), any \( i \in \{2, 3, \ldots\} \), any \( N \times 1 \) dimensional vectors \( \theta, \eta \) and \( \mathbf{a} \), such that \( \|\eta\|_1 = O(1), \|\theta\| = O(1) \) and \( \|\mathbf{a}\| = O(1) \), we have

\[
\frac{1}{T} \sum_{t=m_T+1}^{T} \theta^t v_{t-p} \eta^t v_{t-q} - E (\theta^t v_{t-p} \eta^t v_{t-q}) \overset{L_1}{\to} 0, \tag{A.12}
\]

\[
\frac{1}{T} \sum_{t=m_T+1}^{T} \varepsilon_{1,t-p} \theta^t v_{t-q} \overset{L_1}{\to} 0, \tag{A.13}
\]

\[
\frac{1}{T} \sum_{t=m_T+1}^{T} \theta^t v_{t-p} \mathbf{a}^t \varepsilon_{t-q} - E (\theta^t v_{t-p} \mathbf{a}^t \varepsilon_{t-q}) \overset{L_1}{\to} 0, \tag{A.14}
\]

\[
\frac{1}{T} \sum_{t=m_T+1}^{T} \xi_{1,t-p} e_{it} \overset{L_1}{\to} 0, \tag{A.15}
\]

and

\[
\frac{1}{T} \sum_{t=m_T+1}^{T} \xi_{1,t-1} e_{it} \overset{L_1}{\to} 0, \tag{A.16}
\]

where convergence is uniform in \( p \), and \( \mathbf{v}_t \) is defined by (22).

Proof. Let \( T_N = T(N) \) and \( m_{T_N} = m(T_N) \) be any increasing integer valued functions of \( N \) satisfying Assumptions B1 and B2. Define the following two-dimensional array\(^{12}\)

\[
\kappa_{Nt} = \frac{1}{T_N} \theta^t v_{1,t-p} \eta^t v_{t-q},
\]

and the non-stochastic array

\[
c_{Nt} = \frac{1}{T_N},
\]

for any \( t \in \mathbb{Z} \), and any \( N \in \mathbb{N} \). Consider now the triangular array \( \left\{ \begin{array}{c} \kappa_{Nt}, F_{Nt} \\ \{ \kappa_{Nt}, F_{Nt} \}_{t=-\infty}^{T_N} \end{array} \right\}_{N=1}^{\infty} \), where \( \{F_{Nt}\} \) denotes an array of \( \sigma \)-fields that is increasing in \( t \) for each \( N \), and \( \kappa_{Nt} \) is measurable with respect to \( F_{Nt} \). Using independence of \( \mathbf{e}_t = \mathbf{R}_t \mathbf{e}_t \) and \( e_{1t} \) for any \( t, t' \in \mathbb{Z} \) (see Assumption 2), we have

\[
E \left( \kappa_{Nt} \mid F_{N,t-n} \right) = E \left( \sum_{\ell=0}^{\infty} \theta^\ell \Phi^\ell_{1} \mathbf{e}_{t-q-\ell e_{1,t-p}} \mid F_{N,t-n} \right),
\]

\[
= \begin{cases} 0 & \text{for } p < n \\ \sum_{\ell=\ell_1(n,q)}^{\infty} \theta^\ell \Phi^\ell_{1} \mathbf{e}_{t-q-\ell e_{1,t-p}} & \text{for } p \geq n \end{cases},
\]

where

\[
\ell_1(n,q) = \max \{n-q,0\}.
\]

\(^{12}\)Note that \( \kappa_{Nt} \) is also a function of \( p \) and \( q \) but we omit these subscripts to simplify notations.
Also,
\[
\sup_{p \in \{0, 1, \ldots\}} E \left\{ \left[ E \left( \frac{\kappa_{N_1}}{c_{N_1}} | \mathcal{F}_{t-n} \right) \right]^2 \right\} = \sigma_{c_1}^2 \sum_{\ell = \ell_2(p,n)}^{\infty} \theta' \Phi_{\ell - 1} R_{\ell - 1} E (\varepsilon_t \varepsilon_{t-\ell}) R_{\ell - 1} \Phi_{\ell - 1} \theta, \\
\leq \zeta_{nq},
\]
where
\[
\zeta_{nq} = \sigma_{c_1}^2 ||\text{Var}(\varepsilon_t)|| \cdot ||R_{\ell - 1}||^2 ||\theta||^2 \sum_{\ell = \ell_2(n,q)}^{\infty} ||\Phi_{\ell - 1}||^{2\ell}.
\]
Condition (11) of Assumption 2 implies \( ||R_{\ell - 1}|| \leq ||R_{\ell - 1}||_1 ||R_{\ell - 1}||_\infty = O(1) \), \( \sigma_{c_1}^2 < K \) and \( ||\text{Var}(\varepsilon_t)|| < K \) by condition (10) of Assumption 2, and \( ||\Phi_{\ell - 1}|| \leq \sqrt{||\Phi_{\ell - 1}||_1 ||\Phi_{\ell - 1}||_\infty} \leq \rho < 1 \) under Assumption 4, condition (16). Since also \( ||\theta|| = O(1) \), it follows that (for any fixed \( q \in \mathbb{N}_0 \))
\[
\zeta_{0,q} < K \quad \text{and} \quad \zeta_{nq} \to 0 \quad \text{as} \quad n \to \infty.
\]
Therefore, array \( \{\kappa_{N_1}/c_{N_1}\} \) is uniformly bounded in \( L_2 \) norm, which establishes uniform integrability. Furthermore, using Liapunov’s inequality, two-dimensional array \( \{\kappa_{N_1}, \mathcal{F}_{N_1}\} \) is \( L_1 \)-mixingale with respect to non-stochastic array \( \{c_{N_1}\} \). Noting that \( \sum_{t=mT_N + 1}^{T_N} c_{N_1} = \left[ \varepsilon_t \varepsilon_{t-q} - E (\varepsilon_t \varepsilon_{t-q}) \right], \)
for any \( t \in \mathbb{Z} \), and any \( N \in \mathbb{N} \). Again let \( \{\mathcal{F}_{N_1}\} \) denote array of \( \sigma \)-fields that is increasing in \( t \) for each \( N \) and \( \kappa_{N_1} \) is measurable with respect to \( \mathcal{F}_{N_1} \). We have
\[
E \left( \frac{\kappa_{N_1}}{c_{N_1}} | \mathcal{F}_{N,t-n} \right) = \left\{ \left[ \sum_{\ell = \ell_2(p,n)}^{\infty} \theta' \Phi_{\ell - 1} R_{\ell - 1} [\varepsilon_t - \varepsilon_{t-\ell}] \varepsilon_{t-\ell} - E (\varepsilon_t \varepsilon_{t-\ell}) \right] \right\},
\]
for \( q \geq n \),
\[
0 \quad \text{for} \quad q < n.
\]
where
\[
\ell_2(p,n) = \max \{n-p, 0\}.
\]
Define
\[
z_{tpql} = \left( \theta' \Phi_{\ell - 1} R_{\ell - 1} \varepsilon_{t-\ell} \right) (a' \varepsilon_{t-\ell}).
\]
Using (A.20) in (A.19), we obtain
\[
E \left\{ \left[ E \left( \frac{\kappa_{N_1}}{c_{N_1}} | \mathcal{F}_{N,t-n} \right) \right]^2 \right\} = \left\{ \left[ \sum_{\ell = \ell_2(p,n)}^{\infty} \sum_{h = \ell_2(p,n)}^{\infty} E (z_{tpql} z_{tpqh}) - E (z_{tpql}) E (z_{tpqh}) \right] \right\},
\]
for \( q \geq n \),
\[
0 \quad \text{for} \quad q < n.
\]
Note that
\[
E (z_{tpql}) = \left\{ \left[ \theta' \Phi_{\ell - 1} R_{\ell - 1} \text{Var}(\varepsilon_t) a \right] \right\}.
\]
\[\text{See Theorem 19.11 in Davidson (1994).}\]
This implies that

\[ \sum_{\ell=t_2(p,n)}^{\infty} E(z_{tpq}) = \begin{cases} \theta^T \Phi_{1-q} R_{-1} \text{Var}(\varepsilon_{t-q}) a & \text{for } p-q \geq \max \{p-n, 0\} \\ 0 & \text{for } p-q < \max \{p-n, 0\} \end{cases}. \]

But

\[ \left\| \theta^T \Phi_{-1} R_{-1} \text{Var}(\varepsilon_{t-q}) a \right\| \leq \|\theta\| \|\Phi_{-1}\| \|R_{-1}\| \|\text{Var}(\varepsilon_{t-q})\| \|a\| \leq K, \]

where as before \( \|\theta\| = O(1), \|a\| = O(1), \|\Phi_{-1}\| \leq \sqrt{\|\Phi_{-1}\|_1 \|\Phi_{-1}\|_{\infty}} \leq \rho < 1 \) (by condition (16) of Assumption 4), \( \|R_{-1}\| \leq \|R_{-1}\|_1 \|R_{-1}\|_{\infty} = O(1) \) (by condition (11) of Assumption 2) and \( \|\text{Var}(\varepsilon_{t-q})\| = O(1) \) (by condition (10) of Assumption 2). It follows that for \( q \geq n \),

\[ \sup_{p \in \{0,1,2,\ldots\}} \sum_{\ell=t_2(p,n)}^{\infty} E(z_{tpq}) \sum_{h=t_2(p,n)}^{\infty} E(z_{tpqh}) < K. \tag{A.22} \]

Using similar arguments (and noting that fourth moments of \( \varepsilon_{it} \) are uniformly bounded in \( i \)), it can be shown that

\[ \sup_{p \in \{0,1,2,\ldots\}} \sum_{\ell=t_2(p,n)}^{\infty} \sum_{h=t_2(p,n)}^{\infty} E(z_{tpq}, z_{tpqh}) < K \text{ for } q \geq n. \tag{A.23} \]

Results (A.21), (A.22) and (A.23) now establish the existence of a non-stochastic array, \( \varsigma_{nq} \), such that

\[ \sup_{p \in \{0,1,2,\ldots\}} E \left( \left\{ E \left( \frac{N_1}{N} \mathcal{F}_N, t-n \right) \right\}^2 \right) < \varsigma_{nq}, \]

where for a fixed \( q \in \{0,1,2,\ldots\} \),

\[ \varsigma_{0q} < K \text{ and } \varsigma_{nq} \to 0 \text{ as } n \to \infty. \]

Therefore, array \( \{\kappa_{N_1}/N_{1-N}\} \) is uniformly bounded in \( L_2 \) norm, which establishes uniform integrability. Furthermore, using Liapunov’s inequality, two-dimensional array \( \{\kappa_{N_1}, \mathcal{F}_{N_1}\} \) is \( L_1 \)-mixingale with respect to non-stochastic array \( \{c_{N_1}\} \). Noting that equations (A.17)-(A.18) hold, it follows that the array \( \{\kappa_{N_1}, \mathcal{F}_{N_1}\} \) satisfies conditions of a mixingale weak law,\(^{14}\) which implies \( \sum_{t=m_T}^{T} \kappa_{N_1} L_1 \to 0 \), uniformly in \( p \) since the upper bound \( \varsigma_{nq} \) does not depend on \( p \). This completes the proof of (A.14).

Results (A.15) and (A.16) can also be established in the similar fashion as result (A.13), but this time we define \( \kappa_{N_t} = \frac{1}{T_N} \xi_{1,t-p} \varepsilon_{it} \) to establish result (A.15), and \( \kappa_{N_t} = \frac{1}{T_N} \xi_{1,t-1} \varepsilon_{it} \) in order to establish result (A.16). Result (A.14) can be established in the same way as Lemma 1 in Chudik and Pesaran (2010). This completes the proof. \( \blacksquare \)

**Lemma A.5** Let assumptions 1-4, B1, and B3 hold. Then for any \( i \in \{1,2,3,\ldots\} \), \( j \in \{2,3,\ldots\} \), \( p,q \in \{0,1,2,\ldots\} \), and any \( N \times 1 \) dimensional vectors \( \theta \) and \( \eta \), such that \( \|\eta\|_1 = O(1) \) and \( \|\theta\|_\infty = O(N^{-1}) \),

\[ \frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} \theta^T \varepsilon_{t-p} \eta \varepsilon_{t-q} - \sqrt{\rho_2} E \left( \sqrt{N} \theta^T \varepsilon_{t-p} \eta \varepsilon_{t-q} \right) \overset{L_1}{\to} 0, \tag{A.24} \]

\[ \frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} \eta^T \varepsilon_{t-p} \eta \varepsilon_{t-q} - \sqrt{\rho_2} E \left( \sqrt{N} \varepsilon_{t-p} \eta \varepsilon_{t-q} \right) \overset{L_1}{\to} 0, \tag{A.25} \]

\[ \frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} \varepsilon_{1,t-p} \theta \varepsilon_{t-q} \overset{L_1}{\to} 0, \tag{A.26} \]

\[ \frac{1}{\sqrt{T}} \sum_{t=m_T+1}^{T} \varepsilon_{1,t-p} \varepsilon_{1,t-q} \overset{L_1}{\to} 0. \tag{A.27} \]

\(^{14}\)See Theorem 19.11 in Davidson (1994).
\[
\frac{1}{\sqrt{T}} \sum_{t=m+1}^{T} \theta' \nu_{t-p} \epsilon_{t-q} - \sqrt{\varphi_2} E \left( \sqrt{N} \theta' \nu_{t-p} \epsilon_{t-q} \right) \overset{L_1}{\to} 0, \\
\] (A.28)

and
\[
\frac{1}{\sqrt{T}} \sum_{t=m+1}^{T} v_{1, t-p} \epsilon_{t-q} \overset{L_1}{\to} 0, \\
\] (A.29)

where convergence is uniform in \( p \), \( \nu_t \) is defined by equation (22), \( \epsilon_t \) is defined by (20), and \( \varphi_2 = \lim(T/N) \) as \( (N,T) \xrightarrow{d} \infty \).

**Proof.** We have
\[
\frac{1}{\sqrt{T}} \sum_{t=m+1}^{T} \theta' \nu_{t-p} \eta' \nu_{t-q} = \frac{1}{T} \left( \frac{1}{T} \sum_{t=m+1}^{T} \left( \sqrt{N} \theta' \nu_{t-p} \eta' \nu_{t-q} \right) \right), \\
\] (A.30)

where
\[
\left\| \sqrt{N} \theta \right\| = \sqrt{N \left\| \theta \right\|_{\infty} \left\| \theta \right\|_1} = O(1), \\
\] (A.31)

Using now result (A.12) of Lemma A.4 yields
\[
\frac{1}{T} \sum_{t=m+1}^{T} b' \nu_{t-p} \eta' \nu_{t-q} - E \left[ b' \nu_{t-p} \eta' \nu_{t-q} \right] \overset{L_1}{\to} 0 \text{ uniformly in } p, \\
\] (A.32)

under Assumptions B1 and B2, where \( b = \left( \sqrt{N} \theta \right)' \), and \( \| b \| = O(1) \) by (A.31). Multiplying (A.32) by \((T/N)^{1/2}\), and noting that Assumption B3 is a special case of Assumption B2, where \( (N,T) \xrightarrow{d} \infty \) at any rate, and that under Assumption B3,
\[
\sqrt{\frac{T}{N}} \to \sqrt{\varphi_2} < \infty, \\
\]
we obtain
\[
\frac{1}{\sqrt{T}} \sum_{t=m+1}^{T} \theta' \nu_{t-p} \eta' \nu_{t-q} - \sqrt{\varphi_2} E \left( \sqrt{N} \theta' \nu_{t-p} \eta' \nu_{t-q} \right) \overset{L_1}{\to} 0 \text{ uniformly in } p, \\
\]
under Assumptions B1 and B3, as desired. This completes the proof of (A.24). Similarly, result (A.26) follows directly from result (A.13). Result (A.28) can also be established in a similar way by using (A.14) and noting that \( \epsilon_{t-q} = a' \epsilon_{t-q} \) for \( a = R'_{-1} s \), and that \( \| R'_{-1} s \| \leq \sqrt{\| R_{-1} \|_1 \| R_{-1} \|_{\infty}} = O(1) \) by condition (11) of Assumption 2.

To establish result (A.27), we make use of equation (30), which implies
\[
u_{1t} = r'_{-1} \epsilon_t + \phi'_{-1} \nu_{t-1}, \\
\] (A.33)

where \( r'_{-1} \epsilon_t = \epsilon_{1t} \) and vector \( \phi_{-1} \) satisfies
\[
\left\| \phi_{-1} \right\|_{\infty} = O \left( N^{-1} \right), \\
\] (A.34)

by condition (5) of Assumption 1. Using result (A.26) for \( \theta = \phi_{-1} \), we have
\[
\frac{1}{\sqrt{T}} \sum_{t=m+1}^{T} \epsilon_{1, t-p} \phi'_{-1} \nu_{t-q} \overset{L_1}{\to} 0 \text{ uniformly in } p, \\
\] (A.35)

for any \( p, q \in \{ 0, 1, 2, \ldots \} \), under Assumptions B1 and B3. Similarly, \( r_{-1} \) satisfies
\[
\left\| r_{-1} \right\|_{\infty} = O \left( N^{-1} \right), \\
\] (A.36)

by condition (12) of Assumption 2. Noting that \( \nu_t \) reduces to
\[
u_t = \sum_{t=0}^{\infty} \Phi'_{-1} R_{-1} \epsilon_t = \epsilon_t \text{ for } \Phi_{-1} = 0 \text{ and } R_{-1} = I_{-1}, \\
\]
where \( I_{-1} \) is identity matrix with the first column replaced by zeros, result (A.26) implies (for \( \theta = r_{-1}, \phi_{-1} = 0 \) and
that
\[
\frac{1}{\sqrt{T}} \sum_{t=mT+1}^{T} \varepsilon_{1,t-p} \varepsilon_{1,t-q} \overset{L^1}{\to} 0, \text{ uniformly in } p, \tag{A.37}
\]
for any \(p, q \in \{0, 1, 2, \ldots\}\), under Assumptions B1 and B3. (A.33), (A.35), and (A.37) now establish (A.27), as desired.

Result (A.29) is established in a similarly by making use of (A.28) and (A.33). For \(\theta = \phi_{-1}\) (see (A.34)), (A.28) implies
\[
\frac{1}{\sqrt{T}} \sum_{t=mT+1}^{T} \phi_{-1}'(t) \varepsilon_{t-p} \varepsilon_{t-q} - \sqrt{2 \pi} E \left( \sqrt{N} \phi_{-1}' \varepsilon_{t-p} \varepsilon_{t-q} \right) \overset{L^1}{\to} 0 \text{ uniformly in } p, \tag{A.38}
\]
under Assumptions B1 and B3, where
\[
E \left( \sqrt{N} \phi_{-1}'(t) \varepsilon_{t-p} \varepsilon_{t-q} \right) = \left\{ \begin{array}{ll}
\sqrt{N} \phi_{-1}' \Phi_P^{-1} E (\varepsilon_{t-p} \varepsilon_{t-q}) & \text{for } q \geq p \\
0 & \text{for } q < p
\end{array} \right., \tag{A.39}
\]
under Assumptions B1 and B3.

For \(\theta = \phi_{-1}\) (noting that \(\phi_{-1}\) satisfies (A.34)) and for any vector \(\eta\) such that \(\|\eta\|_1 = O(1)\), (A.24) implies
\[
\frac{1}{\sqrt{T}} \sum_{t=mT+1}^{T} \phi_{-1}'(t) \varepsilon_{t-p} \varepsilon_{t-q} - \sqrt{2 \pi} E \left( \sqrt{N} \phi_{-1}' \varepsilon_{t-p} \varepsilon_{t-q} \right) \overset{L^1}{\to} 0 \text{ uniformly in } p, \tag{A.40}
\]
under Assumptions B1 and B3.

Result (A.25) is also established by making use of equation (A.33). For \(\theta = \phi_{-1}\) (noting that \(\phi_{-1}\) satisfies (A.34)) and for any vector \(\eta\) such that \(\|\eta\|_1 = O(1)\), (A.24) implies
\[
\frac{1}{\sqrt{T}} \sum_{t=mT+1}^{T} \phi_{-1}'(t) \varepsilon_{t-p} \eta' \varepsilon_{t-q} - \sqrt{2 \pi} E \left( \sqrt{N} \phi_{-1}' \varepsilon_{t-p} \eta' \varepsilon_{t-q} \right) \overset{L^1}{\to} 0 \text{ uniformly in } p, \tag{A.43}
\]
under Assumptions B1 and B3. Result (A.14) of Lemma A.4 implies by setting \(a = \sqrt{N} \phi_{-1}\) and noting that \(\|a\| = \sqrt{N} \|\phi_{-1}\| = \sqrt{N} \|\phi_{-1}\|_\infty \|\phi_{-1}\|_1 = O(1)\) (see (A.36)), we have
\[
\frac{1}{\sqrt{T}} \sum_{t=mT+1}^{T} \theta'(t) \varepsilon_{t-p} \sqrt{N} \phi_{-1} \varepsilon_{t-q} - E \left( \theta'(t) \varepsilon_{t-p} \sqrt{N} \phi_{-1} \varepsilon_{t-q} \right) \overset{L^1}{\to} 0 \text{ uniformly in } p, \tag{A.44}
\]
under Assumptions B1, and B2. Using same arguments as in (A.30), it follows from (A.44) that
\[
\frac{1}{\sqrt{T}} \sum_{t=mT+1}^{T} \theta'(t) \varepsilon_{t-p} \phi_{-1} \varepsilon_{t-q} - \sqrt{2 \pi} E \left( \theta' \varepsilon_{t-p} \sqrt{N} \phi_{-1} \varepsilon_{t-q} \right) \overset{L^1}{\to} 0 \text{ uniformly in } p, \tag{A.45}
\]
under Assumptions B1, and B3. (A.33), (A.43) and (A.45) establish (A.25), as desired. This completes the proof. 

**Lemma A.6** Suppose that Assumptions 1 to 4 hold. Then for any \(i \in \mathbb{N}\), any \(p \in \{0, 1, 2, \ldots\}\), and any \(N \times 1\)
dimensional vector $\theta$ such that $\|\theta\|_\infty = O \left(N^{-1}\right)$,

$$E \left(s'_i v_{t-p} \theta' v_{t-1} \right) = O \left(N^{-1}\right),$$

(A.46)

and

$$E \left(s'_i v_{t-p} v_{t+1} \right) = O \left(N^{-1}\right),$$

(A.47)

where $s_i$ is an $N \times 1$ dimensional selection vector with $s_{ij} = 0$ for $j \neq i$ and $s_{ii} = 1$, and $v_t$ is defined by equation (22).

**Proof.** We have

$$s'_i v_{t-p} \theta' v_{t-1} = s'_i v_{t-p} v'_{t-1} \theta = \sum_{t=0}^{\infty} s'_i \Phi^t R_{-1} \xi_{t-p-\ell} \sum_{t=0}^{\infty} \epsilon'_{t-\ell} R'_{-1} \Phi^{\ell} \theta.$$  \hspace{1cm} (A.48)

Taking expectations of (A.48) and noting that $\epsilon_t$ is independently distributed of $\epsilon_{t'}$ for any $t \neq t'$, we obtain

$$E \left(s'_i v_{t-p} \theta' v_{t-1} \right) = \sum_{t=\max(1,p)}^{\infty} s'_i \Phi^t R_{-1} E \left(\epsilon_{t-\ell} \epsilon'_{t-\ell} \right) R'_{-1} \Phi^{\ell} \theta \leq \|R_{-1}\|_\infty \|R_{-1}\|_1 \|\theta\|_\infty \|\text{Var} \left(\epsilon_t\right)\|_\infty \sum_{t=\max(1,p)}^{\infty} \|\Phi^{\ell}\|_\infty \|\epsilon\|_1 \|\Phi^{\ell}\|_1$$

where $\|R_{-1}\|_\infty \|R_{-1}\|_1 = O \left(1\right)$ by condition (11) of Assumption 2, $\|\theta\|_\infty = O \left(N^{-1}\right)$, $\|E \left(\epsilon_t \epsilon_t\right)\|_\infty = \|\text{Var} \left(\epsilon_t\right)\|_\infty = O \left(1\right)$ by condition (10) of Assumption 2, and $\|\Phi^{\ell}\|_\infty \leq \rho < 1$, $\|\Phi^{\ell}\|_1 \leq \rho < 1$ by condition (16) of Assumption 4. It follows that $E \left(s'_i v_{t-p} \theta' v_{t-1} \right) = O \left(N^{-1}\right)$, as required.

To establish result (A.47), we make use of equation (A.33). We have

$$E \left(s'_i v_{t-p} v_{t+1} \right) = E \left(s'_i v_{t-p} \epsilon_{t-1} \epsilon_t \right) + E \left(s'_i v_{t-p} \phi'_{t-1} v_{t-1} \right).$$

Noting that $\|\phi_{t-1}\|_\infty = O \left(N^{-1}\right)$ by condition (5) of Assumption 1, result (A.46) for $\theta = \phi_{t-1}$ implies $E \left(s'_i v_{t-p} \phi_{t-1} v_{t-1} \right) = O \left(N^{-1}\right)$. Furthermore,

$$E \left(s'_i v_{t-p} \epsilon_{t-1} \epsilon_t \right) = \begin{cases} 0 & \text{for } p > 0 \\ s'_i R_{-1} E \left(\epsilon_{t-1} \epsilon_t \right) r_{-1} & \text{for } p = 0 \end{cases},$$

where

$$s'_i R_{-1} E \left(\epsilon_{t-1} \epsilon_t \right) r_{-1} \leq \|R_{-1}\|_\infty \|\text{Var} \left(\epsilon_t\right)\|_\infty \|r_{-1}\|_\infty = O \left(N^{-1}\right),$$

using the same arguments as in derivation of (A.46) and noting that $\|r_{-1}\|_\infty = O \left(N^{-1}\right)$ by condition (12) of Assumption 2. It follows that $E \left(s'_i v_{t-p} v_{t+1} \right) = O \left(N^{-1}\right)$, as required. \hspace{1cm} $\blacksquare$
