# Employment Growth, Inflation and Output Growth: Was Phillips Right? Evidence from a Dynamic Panel

## Abstract

In this paper we analyse the short- and long-run relationship between employment growth, inflation and output growth in Phillips' tradition. For this purpose we apply FMOLS, DOLS, PMGE, MGE, DFE, and VECM methods to a nonstationary heterogeneous dynamic panel including annual data for 119 countries over the period 1970-2010, and also carry out multivariate Granger causality tests. The empirical results strongly support the existence of a single cointegrating relationship between employment growth, inflation and output growth with bidirectional causality between employment growth and inflation as well as output growth, giving support to Phillips' Golden Triangle theory.

JEL-Code: C230, E240, E310, E600.

Keywords: employment growth, inflation, output growth, Golden Triangle theory.

## **I. INTRODUCTION**

In his famous contributions Phillips (1958, 1962) emphasised the importance of analysing the quantitative relationship between employment growth, inflation and output growth (the three nodes of the so-called Golden Triangle's internal equilibrium). In his model macroeconomic instability and failures with the associated problems (unemployment, inflation and stagnation) arise when economies move along a non-optimal (golden disequilibrium) path: unless the quantitative dynamic relationships between these variables are known exactly by policy makers, their actions are likely to result in an "overshooting" or "undershooting" of the targeted "equilibrium". Moreover, without this knowledge, it is not even possible to choose optimally the particular inflation rate, level of economic activity or "natural rate of unemployment" that should be targeted. Finally, a proper understanding of the employment/inflation/output relationship might also be instrumental to avoiding or at least alleviating cycles.

This paper is a comprehensive study of both the short- and long-run relationships between these three variables. It contributes to the literature on the Golden Triangle theory by analysing annual data for a panel of 119 countries over the period 1970-2010, and applying state-of-the art econometric methods for nonstationary heterogeneous panels. Specifically, the Nyblom-Harvey, Fisher-Johansen, Pedroni, Westerlund and Kao multivariate cointegration tests are carried out, and the cointegrating vectors are estimated using FMOLS, PMGE, MGE, DFE, VECM methods to deal with possible endogeneity and stationarity issues. Moreover, causality tests are conducted in the context of a panel VECM.

The layout of the paper is as follows. Section 2 briefly reviews the relevant literature. Section 3 describes the data and the econometric framework. Section 4 presents the empirical results. Section 5 offers some concluding remarks.

## **II. LITERATURE REVIEW**

The two seminal studies by Phillips on the relationship between unemployment and the rate of change of nominal wages in the United Kingdom (1958) and that between employment growth, inflation, and output growth (1962) are amongst the most frequently cited articles in economics. Famously, Phillips (1962) argued:

“It is my belief that one of the main reasons for the difficulties that have been experienced in devising and implementing appropriate economic policies is lack of adequate quantitative knowledge and understanding on how the economic system works. (...) But in order to bring this knowledge to bear on the problem of formulating and attaining a consistent set of policy objectives we require also knowledge of the quantitative relations between economic variables. In particular it is necessary to know what quantitative relations hold between those economic variables which are either the objectives of policy or the instruments through which we attempt to attain the objectives.”

Several studies have subsequently analysed the relationship between unemployment and gross domestic product, unemployment, and inflation. A few examples are Okun (1981) and Tobin (1982, 1987, 1996), who focused on the inflation-unemployment trade-off, whilst Kaldor (1992) examined the role of wages, and Phelps (1967, 1998) and Friedman (1968, 1971) highlighted the disagreement on the role of different policy instruments in achieving the goals of economic policy. Related papers are Gordon (1991, 1977), Phelps and Zoega (1998), Nickell (1998),

Lorenzoni (2010), Acemoglu et al. (1994), Adams and Coe (1990), Aguiar and Martins (2005), Altig et al. (1997), Apergis and Rezitis (2003), Okun (1980), Samuelson (2008), and Thirlwall (1969). Among very recent empirical studies Hooker (2002) and Nakov and Pescatori (2010) both offer evidence of a backward-looking Phillips' curve for countries other than the US. Only few papers exist on the simultaneous relationship between all three variables (employment growth, inflation and output growth) – see Raurich and Sorolla, 2000, and Scott and McKean, 1964.

### III. DATA AND ECONOMETRIC METHODS

#### A. Data

Our dataset is a balanced panel with annual data on employment, prices and output from 1970 to 2010 for 119 countries.<sup>1</sup> The variables are in annual percentage changes. The data sources are the USDA International macroeconomic dataset (historical data files) and the Conference board total economy database 2011.

#### B. Econometric Methods and Models

We investigate the relationship between  $y_{it}$ , the annual growth rate of real output in country  $i$  and year  $t$ ;  $p_{it}$ , the annual inflation rate, and  $e_{it}$ , the annual growth rate of employment, estimating the following model:

$$y_{it} = \beta_{0i} + \beta_{1i}p_{it} + \beta_{2i}e_{it} + u_{it} \quad (1)$$

where  $u_{it}$  is the error term. Since we want to explore the direction of causality as well we also specify the models

$$p_{it} = \beta_{0i} + \beta_{1i}y_{it} + \beta_{2i}e_{it} + u_{it} \quad (2)$$

and

$$\mathbf{e}_{it} = \beta_{0i} + \beta_{1i}p_{it} + \beta_{2i}y_{it} + u_{it} \quad (3)$$

As a first step, the order of integration of the series should be established by means of panel unit root tests. Then, if the evidence suggests nonstationarity of the variables, the existence of cointegrating relationships between them should be tested to justify the above specifications. Subsequently, Granger causality tests can also be carried out to analyse the causal linkages between these three variables.

### *B1. Unit Root Tests*

To check the stationarity of the series in the panel under cross-sectional dependence we use first- and second-generation unit root tests (see Im, Pesaran and Shin, (2003). First-generation panel unit roots tests include Levin and Lin (1992,1993), Levin, Lin and Chu (2002), Harris and Tzavalis (1999), Im, Pesaran and Shin (1997, 2002, 2003), Maddala and Wu (1999), Choi (1999, 2001), Hadri (2000), whilst second-generation tests are those of Bai and Ng (2001, 2004), Moon and Perron (2004a), Phillips and Sul (2003a), Pesaran (2003, 2007), Choi (2002), Breitung and Das (2005).

The Levin and Lin (1992, 1993) test takes the form (LLC)

$$\Delta y_{i,t} = \alpha_i + \rho y_{i,t-1} + \sum_{z=1}^p \beta_{i,z} \Delta y_{i,t-z} + \varepsilon_{i,t} \quad (4)$$

under the unit root null.

The Im, Pesaran and Shin (IPS) test allowing for heterogeneity in  $\rho_i$  (Christophe Hurlin, Valerie Mignon, 2006) is specified as follows:

$$\Delta y_{i,t} = \alpha_i + \rho_i y_{i,y-1} + \sum_{z=1}^{\rho_i} \beta_{i,z} \Delta y_{i,t-z} + \varepsilon_{i,t} \quad (5)$$

Breitung (2000) developed the following t-ratio test for the presence of non-stationarity in the panel data

$$\Delta y_{it} = \mathfrak{S}_t \left[ \Delta y_{it} - \frac{1}{T-t} (\Delta y_{it+1} + \dots + \Delta y_{iT}) \right] \quad (6)$$

although Moon, Perron and Phillips (2006) pointed out the limitations of this test in terms of asymptotic power properties.

Hadri (2000) proposed a different panel unit root test based on the null of stationarity allowing for individual specific variances and correlation patterns. His test takes the form

$$y_{it} = \delta_{mi} d_{mt} + \varepsilon_{it} \quad (7)$$

Hlouskova and Wagner (2006) showed that Hadri's test tends to reject stationarity most of the times in the presence of autocorrelation. Baum (2001) proposed a more powerful version of this test (under the null that the error process is homoscedastic across the panel or heteroscedastic across countries and there is serial dependence in the disturbances). Maddala and Wu (1999) proposed a Fisher's type test based on p-values from individual root tests taking the form (ADF)

$$-2 \sum_{i=1}^N (\ln p_i) \sim \chi^2(2N) \quad (8)$$

while Choi (2001) adopted the following specification (PP):

$$P_m = \frac{1}{2\sqrt{N}} \sum_{i=1}^N (-2 \ln p_i - 2) \quad (9)$$

Finally, Pesaran (2007) suggested using instead a cross-sectionally augmented IPS test (CIPS)

$$CIPS(N, T) = N^{-1} \sum_{i=1}^N \hat{t}_i^*(N, T) \quad (10)$$

which is valid under cross-sectional dependence and individual-specific error serial correlation. Breitung and Westerlund (2009) as well as Eberhardt (2009) discuss panel unit root tests in the presence of parameter heterogeneity, cross-section dependence, and especially the issue of cross-section cointegration.

All unit root test results are presented in Table A1. We find evidence of both stationary and non-stationary individual country series. Using Baum's version of Hadri's test the null of stationarity in our panel is rejected at the 1% level under homoscedastic, heteroscedastic and serial dependence assumptions. Overall, the unit root test results are inconclusive owing to the fact that the panel includes a mixture of I(0) and I(1) series. Breuer and McNown (2003) discuss the low power of panel unit root tests in such a case, and Westerlund (2008) shows that the empirical failure to reject the unit root null does not definitely establish its presence. Because of the mixed unit root test results we test for possible cointegration using Pedroni's (2001) FMOLS and DOLS individual and panel tests. The results (not reported here for reasons of space) overwhelmingly reject the null hypothesis of no cointegration between employment growth, inflation and output growth (only for three countries in the panel the null of no cointegration cannot be rejected). Given the evidence of nonstationarity provided by Hadri's test under heterogeneity and serial correlation and that of cointegration produced by Pedroni's FMOLS and DOLS tests, we carry out further cointegration tests under the assumption that the individual series are I(1).

## B2. Testing for Cointegration and Dynamic Panel Data Estimation

We test for the existence of a long-run relationship between employment growth, inflation and output growth using the Nyblom-Harvey, Fisher-Johansen, Pedroni, Westerlund and Kao cointegration tests. The panel cointegration test results are presented in Table A2 with the lag length chosen on the basis of the Akaike information criterion (AIC) with individual intercepts and trends.

Nyblom and Harvey (2000) test for common stochastic trend in the panel under the null of zero common trends as a proxy for cointegration relationship. Their test takes the form

$$\kappa_{\perp} = \frac{1}{T^2} \sum_{t=1}^T \mathfrak{S}_t \hat{\Xi}^{-1} \mathfrak{S}_t \xrightarrow{d} \int_0^1 W(s)' W(s) ds \quad (11)$$

to test for common trends among the variables.

Maddala and Wu (1999) develop a Fisher and Johansen test of the form:

$$\Delta Y_{i,t} = \Pi_i y_{i,t-1} + \sum_{k=1}^n T_k \Delta Y_{i,t-k} + u_{i,t} \quad (12)$$

Pedroni's (2001) tests for cointegration are based on the estimated residual as follows:

$$\mathbf{e}_{it} = \rho_i \mathbf{e}_{it-1} + \sum_{j=1}^{p_i} \psi_{ij} \Delta \mathbf{e}_{it-j} + v_{it} \quad (13)$$

Kao (1999) developed a similar residual-based panel cointegration test under the null that the residuals are nonstationary with homogenous variance of the innovation process  $\varepsilon_{it}$

$$\hat{\varepsilon}_{it} = \rho \hat{\varepsilon}_{it-1} + \sum_{j=1}^p v_j \Delta \hat{\varepsilon}_{it-j} + v_{it} \quad (14)$$

Persyn (2008) and Westerlund (2007) suggest an error-correction panel cointegration test for the presence of cointegration both at country and panel level:

$$\Delta y_{it} = \delta'_i d_t + \alpha_i y_{it-1} + \lambda'_i x_{it-1} + \sum_{j=1}^p \alpha_{ij} \Delta y_{it-j} + \sum_{j=0}^p \gamma_{ij} \Delta x_{it-j} + e_{it} \quad (15)$$

The test results strongly reject the null of no cointegration in favour of the existence of a long-run relationship between employment growth, inflation and output growth in the panel, consistently with the previously discussed panel FMOLS and DOLS findings. Having established cointegration, we estimate the long-run models (1), (2) and (3) using FMOLS (fully modified OLS), DOLS (dynamic OLS), PMGE (pooled mean group estimator), MG (mean group) and DFE (dynamic fixed effect) methods. Following Pedroni (2001), the FMOLS estimator corrected for heterogeneity (in the fixed effects and the short run) and the OLS estimator adjusted for serial correlation take the form

$$\hat{\beta}_{NT}^* - \beta = \left( \sum_{i=1}^N \hat{L}_{22i}^{-2} \sum_{t=1}^T (x_{it} - \bar{x}_i)^2 \right)^{-1} \sum_{i=1}^N \hat{L}_{11i}^{-1} \hat{L}_{22i}^{-1} \left( \sum_{t=1}^T (x_{it} - \bar{x}_i) \mu_{it}^* - T \hat{\gamma}_i \right) \quad (16)$$

where  $\hat{L}_i$  is a lower triangular decomposition of the covariance matrix  $\Omega_i$ ,  $\Gamma_i$  a weighted sum of autocovariances, with  $\hat{L}_{11i} = (\Omega_{11i} - \Omega_{21i}^2 / \Omega_{22i})^{1/2}$  and  $L_{22i} = \Omega_{22i}^{1/2}$  are the long-run standard errors of the conditional process. Here  $\hat{\beta}_{NT}^*$  is a fully modified estimator (FMOLS) with the individual specific mean of the form

$$\mu_{it}^* = \mu_{it} - \frac{\hat{L}_{21i}}{\hat{L}_{22i}} \Delta x_{it}, \hat{\gamma}_i \equiv \hat{\Gamma}_{21i} + \hat{\Omega}_{21i}^o - \frac{\hat{L}_{21i}}{\hat{L}_{22i}} (\hat{\Gamma}_{22i} + \Omega_{22i}^o) \quad (17)$$

Pedroni (2001) proposes a dynamic OLS estimator (DOLS) of the form

$$\hat{\beta}_{i,DOLS} = \left[ N^{-1} \sum_{i=1}^N \left( \sum_{t=1}^T z_{it} z_{it}' \right)^{-1} \left( \sum_{t=1}^T z_{it} \tilde{y}_{it} \right) \right]_1 \quad (18)$$

where  $z_{it}$  is the  $2(K+1) \times 1$  vector of regressors

$$z_{it} = \{ (x_{it} - \bar{x}_i), \Delta x_{it-K}, \dots, \Delta x_{it+K} \}; \tilde{y}_{it} = y_{it} - \bar{y}_i$$

correcting for endogeneity and serial correlation in the panel by including leads and lags of differenced I(1) regressors. Since we are interested not only in the long-run equilibrium relationship but also in short-run and Granger causality relations between the variables we use PMG, MG, DSE and VECM estimations methods as well. Following the approach of Pesaran, Shin (1995) and Smith (1999) for nonstationary dynamic panels with heterogeneous parameters we estimate our dynamic panel using MG, PMG and DSE in the form:

$$\Delta y_{it} = \phi(y_{i,t-1} - \phi' x_{it}) + \sum_{j=1}^{p-1} \lambda_{ij}^* \Delta y_{i,t-1} + \sum_{j=0}^{q-1} \delta_{ij}' \Delta x_{i,t-j} + \mu_i + \varepsilon_{it} \quad (19)$$

Following Pesaran, Shin and Smith (1999) we estimate an ARDL(2,2,2) model

$$y_{it} = \sum_{j=1}^p \lambda_{ij} y_{i,t-j} + \sum_{j=0}^q \delta_{ij}' x_{i,t-j} + \gamma_i' d_t + \varepsilon_{it} \quad (20)$$

where  $i = 1, 2, \dots, 119$  stands for the country;  $t = 1, 2, \dots, 41$  for the time period;  $x_{it} = (k \times 1)$  and  $d_t = (s \times 1)$  for the vectors of explanatory variables (regressors).

Re-parameterising (19) we obtain an error correction model of the form

$$\Delta y_{it} = \phi_i y_{i,t-1} + \beta_i' x_{it} + \sum_{j=1}^{p-1} \lambda_{ij}^* \Delta y_{i,t-j} + \sum_{j=0}^{q-1} \delta_{ij}^* \Delta x_{i,t-j} + \gamma_i' d_t + \varepsilon_{it}$$

$$\text{where } \phi_i = -(1 - \sum_{j=1}^p \lambda_{ij}), \beta_i = \sum_{j=0}^q \delta_{ij}, \lambda_{ij}^* = - \sum_{m=j+1}^p \lambda_{im}, j=1, \dots, p-1 \quad (21)$$

$$\text{and } \delta_{ij}^* = - \sum_{m=j+1}^q \delta_{im}, j=1, \dots, q-1, i=1, \dots, N$$

Following the work of Engle and Granger (1987) we specify a VECM panel model to examine Granger causality relationship between employment growth, inflation and output growth. As in Pedroni (1999, 2004) we estimate the long-run relationship as follows:

$$y_{i,t} = \alpha_i + \delta_i t + \beta_{1i} x_{1i,t} + \beta_{2i} x_{2i,t} + \dots + \beta_{Mi} x_{Mi,t} + e_{i,t} \quad (22)$$

for  $t = 1, \dots, T$ ;  $i = 1, \dots, N$ ;  $m = 1, \dots, M$  with T being the number of observations (time), N the number of individual countries in the panel and M the number of regression variables. After estimating (21) and identifying the long-run relationships, we estimate a panel VECM model

$$\Delta y_{it} = \theta_{1i} + \lambda_{1i} EC_{i,t-1} + \sum_{k=1}^m \theta_{11ik} \Delta y_{i,t-k} + \sum_{k=1}^m \theta_{12ik} \Delta p_{i,t-k} + \sum_{k=1}^m \theta_{13ik} \Delta e_{i,t-k} + u_{1it} \quad (23)$$

and then test for multivariate causality with lag length m (SIC=2) to examine the direction (patterns) of causality between the variables in both the short- and the long-run:

- Unidirectional causality between output growth, employment growth and inflation
- Unidirectional causality between inflation, employment growth and output growth

- Bidirectional causality between output growth, employment growth and inflation
- No causality between output growth, employment growth and inflation

Multivariate causality is tested by means of Wald tests (F tests) of the null  $H_0 : \theta_{12ik}, \theta_{13ik} = 0$ ,  $H_0 : \theta_{22ik}, \theta_{23ik} = 0$ ,  $H_0 : \theta_{31ik}, \theta_{32ik} = 0$  (i.e., the independent variables do not cause the dependent ones in the model) for all  $i$  and  $k$  in (23). To examine the long-run relationship between independent and dependent variables we test  $H_0 : \lambda_{1i}, \lambda_{2i}, \lambda_{3i} = 0$  for all  $i$  and  $k$  in (23) (i.e., no long-run stable relationship between independent and dependent variables in the model).

#### IV. EMPIRICAL RESULTS

In this section we report the results of the PMG, MG, FMOLS, DOLS, Dynamic Fixed Effect and VECM estimation as well as the results of the multivariate Granger causality analysis. Table A3 displays the estimated long-and short-run relationships for individual countries as well as some misspecification tests. The empirical evidence clearly supports the existence of a long-run relationship between employment growth, inflation and output growth in Phillips' tradition in a large panel of countries. This is confirmed by several estimation procedures. The panel results (not presented here) for the FMOLS and DOLS tests for cointegration in heterogeneous panels as in Pedroni (2001) imply that the null  $H_0: \beta_i = 0$  of no cointegration between the three variables is rejected both at individual country and panel level, except for Malta (FMOLS does not reject, DOLS reject), Norway, St. Lucia, Ukraine (both FMOLS and DOLS do not reject). The panel FMOLS and DOLS results without time dummies with  $t$ -statistic = -1589.83 for FMOLS and -

1368.77 for DOLS and with time dummies with  $t$ -statistic = -2722.07 FMOLS and -2141.17 for DOLS strongly support the hypothesis of cointegration.

The fully modified OLS estimates of the cointegration relationship are reported in Table A3 (individual country level) and Table 1 (panel FMOLS). In the case of the panel FMOLS and DOLS (without time trend) analysis the estimated coefficient for inflation is 0.0253 and 0.0294 respectively and is statistically significant in both cases, although with a positive effect on output growth. Panel unit root tests show that the series in the panel share common stochastic trends, and therefore omitting the trend component would generate a bias in both the FMOLS and DOLS estimates. With the inclusion of a time trend the estimated impact of inflation on output growth is, as expected, negative (FMOLS: -0.0087; DOLS: -0.0091) and statistically significant at the 1% level. Employment growth (without a time trend) has a positive effect (FMOLS=0.3469 and DOLS= 0.0968) on output growth that is statistically significant at the 1% level. Its impact on output growth (with a time trend included) is also statistically significant and positive (even larger, with the FMOLS estimate equal to 0.4592 and the DOLS one to 0.3528). At country level, inflation is found to have a negative effect on output growth (in 71 countries) ranging from -0.000 to 0.299 at the 1% significance level. It is noteworthy that this negative impact is mostly present in developing and transition economies, whilst it is positive in most OECD countries (except the UK and the US). Employment growth has a positive and statistically significant impact on output growth at country level (for 85 countries) with coefficient values ranging from 0.000 to 2.217 (Russia). The panel long-run coefficient estimates using MGE and DFE are statistically significant with values for inflation of -0.023 (PMGE) and -0.027 (DFE) respectively, supporting the idea that inflation has a negative effect on output growth. The long-run coefficient for inflation

using MGE is not statistically significant. The Hausman test statistic for choosing between the PMGE and MGE estimators is equal to 3.43, indicating that PMGE is to be preferred as being more efficient under the null that the long-run coefficients are homogenous. Table A3 shows that the PMGE long-run coefficients are in fact statistically significant at country level for both inflation and employment growth. The latter affects output growth positively with statistically significant coefficients of 0.4431 for PMGE and 0.5227 for DFE. The panel VECM results do not differ substantially from the PMGE, MGE, DFE, FMOLS and DOLS ones, with the estimated long-run coefficients being -0.0012 for inflation of -0.0012 and 0.3001 for employment growth (all statistically significant at the 1% level).

Overall, the long-run coefficients for inflation and employment growth converge to the PMGE values of -0.002 and 0.443 respectively. This is an important finding for two reasons. First, it supports empirically the existence of a long-run relationship between employment growth, inflation and output growth as postulated by Phillips (1962) in his Golden Triangle theory. Second, it provides policy-makers with an estimate of the inflation and employment growth effects on output growth. The cointegration results appear to be very robust. For instance, the error correction equations (23) estimates (see Table A3) indicate that  $\lambda$  is statistically significant and negative for all countries in the panel. The same holds for the panel VECM as can be seen from Table 2 (except for the positive values of  $\lambda$  when (p) is the dependent variable). This confirms the existence of a long-run relationship between the three variables. Having already found long-run causality (as implied by the EC coefficients) we are also interested in examining the direction of causality between the variables (see Table 2 and Figure 1).

Figure 1 Panel Data Granger Causality Relations (ECM estimates) for Employment Growth, Inflation and Output Growth

It can be seen that the estimates of equation (23) imply bidirectional (and statistically significant at the 1% level) Granger causality between inflation and output growth ( $p \rightarrow y, y \rightarrow p$ ), and employment growth and output growth as well as inflation ( $e \rightarrow y, y \rightarrow e, e \rightarrow p, p \rightarrow e$ ) in both the short- and long- run. The only exception is the unidirectional short-run causality running from inflation to output growth ( $p \rightarrow y$ ). This is consistent with Phillips' idea that employment growth, inflation and output growth are both policy instruments and targets driven by some kind of mutually self-reinforcing process (bidirectional causality).

	<b>59.4</b>	<b>-29.3</b>	<b>303.0</b>	<b>21.0</b>	<b>6.31</b>	<b>24.1</b>	0.48	<b>-5.65</b>	<b>12.3</b>

Notes: LR, SR, JR and EC stand for long-run, short-run, and joint (both short- and long-run) causality and error-correction coefficients respectively;  $y \rightarrow p$  means that variable y does not Granger cause variable p; coefficients in bold indicate significance at the 1%, 5% level; coefficients in italics indicate significance at the 10% level.

## V. CONCLUSIONS

In his 1962 article Phillips stressed the importance for policy makers of acquiring information about the nature of the quantitative relationship between employment growth, inflation and output growth in order to take appropriate policy measures. Since then many studies have analysed this relationship, but surprisingly

only a few have estimated it allowing for simultaneity (see Raurich and Sorolla, 2000, and Scott and McKean, 1964). To our knowledge, the present paper is the most extensive empirical investigation of this topic, being based on a panel of 119 countries over the time period 1970-2010, and also applying cutting-edge panel econometrics allowing for possible heterogeneity and nonstationarity to examine the existence of long-run relationships between these variables and to obtain accurate estimates of the long-run coefficients at both country and panel level. Further, it investigates causality linkages between these series. Its findings confirm the existence of a long-run relationship as outlined in Phillips' Golden Triangle theory, and also give useful guidance to policy makers on the size of the various effects, enabling them to devise more accurate policies to achieve their targets.

## APPENDIX

Table A1 Panel unit root tests

Variables	LLC		IPS		Breitung	Hadri		ADF		PP
