Abstract

We consider an additive model with second order interaction terms. It is shown how the components of this model can be estimated using marginal integration, and the asymptotic distribution of the estimators is derived. Moreover, two test statistics for testing the presence of interactions are proposed. Asymptotics for the test functions are obtained, but in this case the asymptotics produce inaccurate results unless the number of observations is very large. For small or moderate sample sizes a bootstrap procedure is suggested and is shown to work well on a simulated example. Finally, our methods are illustrated on a five-dimensional production function for a set of Wisconsin farm data. In particular, the separability hypothesis for the production function is discussed. 

Keywords: Testing Additivity, Derivative Estimation, Nonparametric Regression, Additive Models.

1 Introduction

Linearity is often used as a simplifying device in econometric modeling. If a linearity assumption cannot be entertained, even as a rough approximation, a very large class of nonlinear models is subsumed under the general regression model

\[ Y = m(X) + \sigma(X)\varepsilon, \]

where \( X = (X_1, \ldots, X_d) \) is a vector of explanatory variables, and where \( \varepsilon \) is independent of \( X \) with \( E(\varepsilon) = 0 \) and \( Var(\varepsilon) = 1 \). Although in principle this model can be estimated using nonparametric methods, in practice the curse of dimensionality would in general render such a task impractical.

A viable middle alternative in modeling complexity is to let \( m \) be additive, i.e.

\[ m(x) = c + \sum_{\alpha=1}^{d} f_{\alpha}(x_{\alpha}), \]

where the functions \( f_{\alpha} \) are unknown. The additivity assumption has been employed in several areas of economic theory, for example in connection with separability hypotheses for production functions. Traditionally, additive models have been estimated using backfitting (Hastie and Tibshirani 1990), but recently the method of marginal integration (Auestad and Tjøstheim 1991, Linton and Nielsen 1995, Newey 1994, Tjøstheim and Auestad 1994) has attracted a fair amount of attention, an advantage being that an explicit asymptotic theory can be constructed. It should be remarked that important progress has been made recently (Linton, Mammen and Nielsen 1997, Opsomer and Ruppert 1997) in the asymptotic theory of backfitting.

A weakness of the purely additive model is that interactions between the explanatory variables are completely ignored, and in certain econometric contexts - production function modeling being one of them - the absence of interaction terms has been criticized. In this paper we therefore allow for second order pairwise interactions resulting in a model

\[ m(x) = c + \sum_{\alpha=1}^{d} f_{\alpha}(x_{\alpha}) + \sum_{1 \leq \alpha < \beta \leq d} f_{\alpha\beta}(x_{\alpha}, x_{\beta}). \]

Such models have been mentioned in Hastie and Tibshirani (1990) and briefly in Tjøstheim and Auestad (1994) and a hierarchy of increasing order of interactions has been discussed. The main objective of this paper is to consider estimation and testing of the interaction terms using marginal integration theory. Again the latter makes it possible to construct a precise asymptotic theory. An application to testing for the presence of interaction terms in a production function will be given in Section 5.3.

Not surprisingly, the problems of testing and estimation are intimately connected. The estimation theory is used in constructing tests, and once the test has been performed, estimation theory can again be used to construct confidence intervals for the model resulting from the testing procedure.

We construct two basic functionals for testing of the presence of interaction between a pair of variables \((x_{\alpha}, x_{\beta})\). The most obvious one is to estimate \( f_{\alpha\beta} \) and then use a test functional

\[ \int f_{\alpha\beta}^2(x_{\alpha}, x_{\beta})\pi(x_{\alpha}, x_{\beta})dx_{\alpha}dx_{\beta}, \]
where \( \pi \) is an appropriate non-negative weight function. The other functional is based on the fact that \( \partial^2 m / \partial x_\alpha \partial x_\beta \) is zero iff there is no interaction between \( x_\alpha \) and \( x_\beta \). By marginal integration techniques this can be achieved without estimating \( f_{\alpha \beta} \) itself and its derivative, but it does require the estimation of a second order mixed partial derivative of the marginal regressor in the direction \( (x_\alpha, x_\beta) \).

It is well known that the asymptotic distribution of test functionals of the above type is not a very accurate description of the finite sample properties unless the sample size \( n \) is fairly large, see e.g., Hjellvik, Yao and Tjøstheim (1998). As a consequence for a moderate sample size we have adopted a wild bootstrap scheme for constructing the null distribution of the test functional.

Our test is in effect a test of additivity with the added bonus that the alternative is formulated in terms of interactions between pairs of variables. Thus as an outcome of the testing procedure we should be capable of indicating which pairs (if any) of variables should be included to describe the interaction. We again refer to the example of Section 5.3.

Other tests of additivity or interaction terms have been proposed. The one coming closest to ours is a test by Gozalo and Linton (1997), which is based on the differences in modelling \( m \) by a purely additive model as in equation (2) opposed to using the general model (1). The curse of dimensionality may of course lead to bias - as pointed out by the authors themselves. Also, this test is less specific in indicating what should be done if the additivity hypothesis is rejected. A rather different approach to additivity testing (in a time series context) is taken by Chen, Liu and Tsay (1995). Still another methodology is considered by Eubank, Hart, Simpson and Stefanski (1995).

### 2 Some Simple Properties of the Model

In general, \( X = (X_1, X_2, \ldots, X_d) \) represents a sequence of independent identically distributed (i.i.d.) vectors of explanatory variables, \( \varepsilon \) refers to a sequence of i.i.d. random variables independent of \( X \), and such that \( E(\varepsilon) = 0 \) and \( \text{Var}(\varepsilon) = 1 \). In the expression (3) for \( m(x) \), \( c \) is a constant, \( \{f_{\alpha}(\cdot)\}_{\alpha=1}^{d} \) and \( \{f_{\alpha \beta}(\cdot)\}_{\alpha=1}^{d} \) are real-valued unknown functions, and where for \( \alpha = 1, 2, \ldots, d \) one has

\[
Ef_{\alpha}(X_\alpha) = \int f_{\alpha}(x_\alpha) \varphi_\alpha(x_\alpha) dx_\alpha = 0,
\]

and for all \( 1 \leq \alpha < \beta \leq d \),

\[
\int f_{\alpha \beta}(x_\alpha, x_\beta) \varphi_\alpha(x_\alpha) dx_\alpha = \int f_{\alpha \beta}(x_\alpha, x_\beta) \varphi_\beta(x_\beta) dx_\beta = 0,
\]

with \( \{\varphi_{\alpha}(\cdot)\}_{\alpha=1}^{d} \) being marginal densities (assumed to exist) of the \( X_\alpha \)'s. Equations (5) and (6) are identifiability conditions. If one starts with a function of the form given in (3) not necessarily satisfying (5) and (6), the following steps could be taken:

1. Replace all \( \{f_{\alpha \beta}(x_\alpha, x_\beta)\}_{1 \leq \alpha < \beta \leq d} \) by \( \{f_{\alpha \beta}(x_\alpha, x_\beta) - f_{\alpha \alpha}(x_\alpha) - f_{\beta \beta}(x_\beta) + c_{\alpha \beta}\}_{1 \leq \alpha < \beta \leq d} \), where

\[
f_{\alpha \alpha}(x_\alpha) = \int f_{\alpha \beta}(x_\alpha, u) \varphi_\beta(u) du
\]
and every pair \( (x, \beta) \) and let 
\[
f_{\beta, \alpha \beta}(x) = \int f_{\alpha \beta}(u, x) \varphi_{\alpha}(u) du
\]
\[
e_{\alpha, \beta} = \int f_{\alpha \beta}(u, v) \varphi_{\alpha}(u) \varphi_{\beta}(v) dudv
\]
and adjust the \( \{f_{\beta}(x)\}_{\beta=1}^{d} \)'s and the constant term \( e \) accordingly so as to keep \( m() \) the same function;

2. Replace all \( \{f_{\beta}(x)\}_{\beta=1}^{d} \) by \( \{f_{\beta}(x) - e_{\alpha, \beta}\}_{\beta=1}^{d} \), where \( e_{\alpha, \beta} = \int f_{\beta}(u) \varphi_{\beta}(u) du \), and adjust the constant term \( e \) accordingly so as to keep \( m() \) the same function.

Let \( X_d \) be the \((d-1)\)-dimensional random variable obtained by removing \( X_\alpha \) from \( X = (X_1, \ldots, X_d) \), and let \( X_{\alpha \beta} \) be defined analogously. With some abuse of notation we write \( X = (X_\alpha, X_\beta, X_{\alpha \beta}) \) to highlight the directions in \( d \)-space represented by the \( \alpha \) and \( \beta \) coordinates. We denote the marginal density of \( X_\alpha \), that of \( X_{\alpha \beta} \) and of \( X \) by \( \varphi_\alpha(x_\alpha), \varphi_{\alpha \beta}(x_\alpha, x_\beta) \), and \( \varphi(x) \), respectively.

We now define by marginal integration
\[
F_\alpha(x_\alpha) = \int m(x_\alpha, x_\beta) \varphi_{\beta}(x_\beta) dx_\beta,
\]
for every \( 1 \leq \alpha \leq d \)

and
\[
F_{\alpha \beta}(x_\alpha, x_\beta) = \int m(x_\alpha, x_\beta, x_{\alpha \beta}) \varphi_{\alpha \beta}(x_{\alpha \beta}) dx_{\alpha \beta},
\]
for every pair \( 1 \leq \alpha < \beta \leq d \). Denote by \( D_\alpha \) and \( D_{\alpha \beta} \) the subset of \( \{1, 2, \ldots, d\} \) with \( \alpha \), respectively \( \alpha \) and \( \beta \), removed. Moreover, let \( D_{\alpha \beta} = \{((\gamma, \delta) \mid 1 \leq \gamma < \delta \leq d, \gamma \in D_\alpha, \delta \in D_\beta \} \),
\[
D_{\alpha \beta} = \{(\gamma, \delta) \mid 1 \leq \gamma < \delta \leq d, \gamma \in D_\alpha \cap D_\beta, \delta \in D_\alpha \cap D_\beta \}
\]
and
\[
e_{\alpha \beta} = \int f_{\alpha \beta}(u, v) \varphi_{\alpha \beta}(u, v) dudv
\]
for every pair \( 1 \leq \alpha < \beta \leq d \). Then (5) and (6) entail the following lemma.

**Lemma 1**

1) \[
F_\alpha(x_\alpha) = f_\alpha(x_\alpha) + c + \sum_{(\gamma, \delta) \in D_{\alpha \beta}} e_{\gamma \delta}
\]
\[
F_{\alpha \beta}(x_\alpha, x_\beta) = f_{\alpha \beta}(x_\alpha, x_\beta) + f_\alpha(x_\alpha) + f_\beta(x_\beta) + c + \sum_{(\gamma, \delta) \in D_{\alpha \beta}} e_{\gamma \delta}
\]

2) \[
f_{\alpha \beta}(x_\alpha, x_\beta) - F_\alpha(x_\alpha) - F_\beta(x_\beta) + \int m(x) \varphi(x) dx = f_{\alpha \beta}(x_\alpha, x_\beta) + c_{\alpha \beta}
\]

3) \[
e_{\alpha \beta} = \int \{f_{\alpha \beta}(u, x_\beta) - F_\alpha(u)\} \varphi_\alpha(u) du - F_\beta(x_\beta) + \int m(x) \varphi(x) dx
\]
\[
f_{\alpha \beta}(x_\alpha, x_\beta) = F_{\alpha \beta}(x_\alpha, x_\beta) - F_\alpha(x_\alpha) - \int \{f_{\alpha \beta}(u, x_\beta) - F_\alpha(u)\} \varphi_\alpha(u) du
\]
Proof.

1) Both formulas follow from the definitions of $D_{\alpha \alpha}$, $D_{\alpha \beta}$, $c_{\alpha \beta}$ and equations (7) and (8).

2) Note first that the population mean is simply
\[
\int m(x)\varphi(x)dx = c + \sum_{1 \leq \gamma < \ell \leq d} c_{\ell \gamma}.
\]
Using this and the formulas in 1), one arrives at
\[
F_{\alpha \beta}(x_\alpha, x_\beta) - F_\alpha(x_\alpha) - F_\beta(x_\beta) + \int m(x)\varphi(x)dx = f_{\alpha \beta}(x_\alpha, x_\beta) + c_{\alpha \beta},
\]
3) We only need to integrate both sides of the equation in 2) and note that the right hand side comes out as $c_{\alpha \beta}$ because of the identifiability condition (5). The rest follows by the equation in 2). Q.E.D.

We define another auxiliary function
\[
\tilde{f}_{\alpha \beta}(x_\alpha, x_\beta) := F_{\alpha \beta}(x_\alpha, x_\beta) - F_\alpha(x_\alpha) - F_\beta(x_\beta) + \int m(x)\varphi(x)dx = f_{\alpha \beta}(x_\alpha, x_\beta) + c_{\alpha \beta},
\]
which is a convenient substitute for $f_{\alpha \beta}(x_\alpha, x_\beta)$ as shown in the following.

Corollary 1
\[
\tilde{f}_{\alpha \beta}(x_\alpha, x_\beta) \equiv 0 \iff f_{\alpha \beta}(x_\alpha, x_\beta) \equiv 0
\]

Proof.

$\implies$: by the previous lemma, $F_{\alpha \beta}(x_\alpha, x_\beta) - F_\alpha(x_\alpha) - F_\beta(x_\beta) + \int m(x)\varphi(x)dx \equiv 0$ implies $f_{\alpha \beta}(x_\alpha, x_\beta) + c_{\alpha \beta} \equiv 0$, or $f_{\alpha \beta}(x_\alpha, x_\beta) \equiv -c_{\alpha \beta}$, which by (6) gives
\[
0 = \int f_{\alpha \beta}(x_\alpha, x_\beta)\varphi_\alpha(x_\alpha)dx_\alpha = -\int c_{\alpha \beta}\varphi_\beta(x_\beta)dx_\beta = -c_{\alpha \beta}.
\]
and therefore $f_{\alpha \beta}(x_\alpha, x_\beta) \equiv 0$;

$\iff$: first by the definition of $c_{\alpha \beta}$, $f_{\alpha \beta}(x_\alpha, x_\beta) \equiv 0$ gives $c_{\alpha \beta} = 0$, and thus $f_{\alpha \beta}(x_\alpha, x_\beta) + c_{\alpha \beta} \equiv 0$. Q.E.D.

The corollary provides a marginal integration tool for testing the presence of the interaction term $f_{\alpha \beta}(x_\alpha, x_\beta)$:
\[
\int \tilde{f}_{\alpha \beta}^2(x_\alpha, x_\beta)\pi(x_\alpha, x_\beta)dx_\alpha dx_\beta \neq 0
\]
where $\pi(x_\alpha, x_\beta)$ is any weight function. This observation suggests the use of the following statistic for testing of additivity of the $\alpha$-th and $\beta$-th directions:

$$\int \tilde{f}_{\alpha\beta}(x_\alpha, x_\beta) \varphi_{\alpha\beta}(x_\alpha, x_\beta) dx_\alpha dx_\beta$$

where

$$\tilde{f}_{\alpha\beta}(x_\alpha, x_\beta) = \widehat{F}_{\alpha\beta}(x_\alpha, x_\beta) = \widehat{F}_\alpha(x_\alpha) - \widehat{F}_\beta(x_\beta) + \frac{1}{n} \sum_{j=1}^{n} Y_j,$$

with $\widehat{F}_{\alpha\beta}$, $\widehat{F}_\alpha$ and $\widehat{F}_\beta$ being defined in the next section, and where it follows from the strong law of large numbers that

$$\frac{1}{n} \sum_{j=1}^{n} Y_j \stackrel{a.s.}{\to} \int m(x) \varphi(x) dx.$$

As an alternative it is also possible to consider the mixed derivative of $f_{\alpha\beta}$. We will use the notation $f^{(r,s)}_{\alpha\beta}$ to denote the derivative $\frac{\partial^{r+s}}{\partial x_\alpha^{r} \partial x_\beta^{s}} f_{\alpha\beta}$ and analogously $f^{(r,s)}_{\alpha\beta}$ for $\frac{\partial^{r+s}}{\partial x_\alpha^{r} \partial x_\beta^{s}} F_{\alpha\beta}$. We only have to check whether

$$\int \left\{ f^{(1,1)}_{\alpha\beta}(x_\alpha, x_\beta) \right\}^2 \pi(x_\alpha, x_\beta) dx_\alpha dx_\beta$$

is zero which is equivalent to $f_{\alpha\beta} \equiv 0$.

3 The Estimators

3.1 Estimation of interaction

To use the marginal integration type statistic (9), estimators of the interaction terms must be prescribed. Imagine the X-variables to be scaled so that we can choose the same bandwidth $h$ for the directions represented by $\alpha$, $\beta$ and $g$ for $\alpha\beta$. Further, let $K$ and $L$ be kernel functions and define $K_\alpha(\cdot) = \frac{1}{h} K(\cdot/h)$ and $L_\beta(\cdot) = \frac{1}{g} L(\cdot/g)$. We will give more detailed descriptions of the kernels $K$ and $L$ and the bandwidths $h$ and $g$ in the next sections. For ease of notation we use the same letters $K$ and $L$ (and later $K^*$) to denote kernel functions of varying dimensions. It will be clear from the context what the dimensions are in each specific case.

Following the ideas of Linton and Nielsen (1995) and Tjøstheim and Auestad (1994) we estimate the marginal influence of $x_\alpha, x_\beta$ and $(x_\alpha, x_\beta)$ by the integration estimator as follows

$$\widehat{F}_{\alpha\beta}(x_\alpha, x_\beta) = \frac{1}{n} \sum_{i=1}^{n} \widehat{m}(x_\alpha, x_\beta, X_{i\alpha\beta}) \quad \text{and} \quad \widehat{F}_\alpha(x_\alpha) = \frac{1}{n} \sum_{i=1}^{n} \widehat{m}(x_\alpha, X_{i\alpha}),$$

where $X_{i\alpha\beta}$ ( $X_{i\alpha}$ ) is the $i$th observation of $X$ with $X_\alpha$ and $X_\beta$ ( $X_\alpha$ ) removed.

The estimator $\widehat{m}(x_\alpha, x_\beta, X_{i\alpha\beta})$ will be called the pre-estimator in the following. To compute it we make use of a special kind of multidimensional local linear kernel estimation; see Ruppert and Wand (1994) for the general case. We consider the problem of minimizing

$$\sum_{i=1}^{n} \{ Y_i - a_0 - a_1 (X_{i\alpha} - x_\alpha) - a_2 (X_{i\beta} - x_\beta) \}^2 K_h(X_{i\alpha} - x_\alpha, X_{i\beta} - x_\beta) L_\beta(X_{i\alpha\beta} - X_{i\alpha\beta})$$

$$+ \frac{1}{n} \sum_{j=1}^{n} Y_j$$

for the unknown parameters $a_0, a_1, a_2$.
for each \(l\) fixed. Accordingly we define

\[
\hat{m}(x_\alpha, x_\beta, X_{l_\alpha\beta}) = \epsilon_1(Z_{a_0}^T W_{l_{a_\beta}} Z_{a_\beta})^{-1} Z_{a_\beta}^T W_{l_{a_\beta}} Y
\]

in which

\[
Y = (Y_1, \cdots, Y_n)^T,
\]

\[
W_{l_{a_\beta}} = \text{diag}\left\{ \frac{1}{n} K_h(X_{i_\alpha} - x_\alpha, X_{i_\beta} - x_\beta) L_\beta(X_{i_{a_0}} - X_{l_{a_\beta}}) \right\}_{i=1}^n,
\]

\[
Z_{a_\beta} = \begin{pmatrix}
1 & X_{1_\alpha} - x_\alpha & X_{1_\beta} - x_\beta \\
\vdots & \vdots & \vdots \\
1 & X_{n_\alpha} - x_\alpha & X_{n_\beta} - x_\beta
\end{pmatrix},
\]

and \(\epsilon_1 = (1, 0, 0)\). It should be noted that this is a local linear estimator in the directions \(\alpha, \beta\) and a local constant one for the nuisance directions \(\alpha\beta\).

Similarly, to produce the pre-estimator \(\hat{m}(x_\alpha, X_{l_{a}})\), with \(\epsilon_1 = (1, 0)\), we define

\[
\hat{m}(x_\alpha, X_{l_{a}}) = \epsilon_1(Z_{a_0}^T W_{l_{a}} Z_{a})^{-1} Z_{a}^T W_{l_{a}} Y
\]

in which

\[
W_{l_{a_\beta}} = \text{diag}\left\{ \frac{1}{n} K_h(X_{i_\alpha} - x_\alpha) L_\beta(X_{i_{a_0}} - X_{l_{a_\beta}}) \right\}_{i=1}^n,
\]

\[
Z_{a} = \begin{pmatrix}
1 & X_{1_\alpha} - x_\alpha \\
\vdots & \vdots \\
1 & X_{n_\alpha} - x_\alpha
\end{pmatrix},
\]

This estimator results from minimizing

\[
\sum_{i=1}^n \{Y_i - a_0 - a_1(X_{i_\alpha} - x_\alpha)\} \hat{K}_h(X_{i_\alpha} - x_\alpha)L_\beta(X_{i_{a_0}} - X_{l_{a_\beta}}),
\]

which gives a local linear smoother for the direction \(\alpha\) and a local constant one for the other directions.

In order to derive the asymptotics of these estimators we make use of the idea of equivalent kernels; see Ruppert and Wand (1994) and Fan et al. (1993). The main idea is that the local polynomial smoother of degree \(p\) is asymptotically equivalent to, i.e. it has the same leading term as, a kernel estimator with "higher order kernel" given by

\[
K_p^*(u) := \sum_{i=0}^p s_{\nu d} u^d K(u)
\]

for the one dimensional case, where \(S = \left(\int u^{t+s} K(u) du\right)_{0 \leq s, t \leq p}\) and \(S^{-1} = (s_{\nu d})_{0 \leq s, t \leq p}\). Estimates of derivatives of \(m\) can then be obtained by taking different rows of \(S^{-1}\).
For the one dimensional case and \( p = 1 \) we have \( S^{-1} = \begin{pmatrix} 1 & 0 \\ 0 & \mu_2^{-1}(K) \end{pmatrix} \), with \( \mu_2(K) = \int u^2 K(u) du \).

For the two dimensional case with \( p = 1 \) the equivalent kernel is

\[
K^*_v(u,v) := K(u,v) s_\nu(1,u,v)^T, \quad \text{with } s_\nu \text{ being the } (\nu+1)^{th} \text{ row of }
S^{-1} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \mu_2^{-1} & 0 \\ 0 & 0 & \mu_2^{-1} \end{pmatrix}, \quad 0 \leq \nu \leq 2.
\]

To estimate the function \( m \) itself (\( \nu = 0 \)) using a local linear smoother (\( p = 1 \)) we have simply \( K^*_v(u) = K(u) \) and \( K^*_0(u,v) = K(u,v) \), but \( K^*_v \) becomes increasingly important when we estimate derivatives. We will come back to this point in Section 3.2.

We are interested in the asymptotics of the estimator \( \hat{f}_{\alpha\beta}(x, \beta) \) given in (10). We need the following assumptions.

**A1:** The kernels \( K(\cdot) \) and \( L(\cdot) \) are positive, bounded, symmetric, compactly supported and Lipschitz continuous. The bivariate kernel \( K \) is a product kernel such that (with some abuse of notation) \( K(u,v) = K(u)K(v) \), where \( K(u) \) and \( K(v) \) are identical functions with \( \int K(u) du = 1 \). The \( d-1 \), respectively \( d-2 \) dimensional kernel \( L(\cdot) \) is also a product of univariate kernels \( L(u) \) of order \( q \geq 2 \), i.e.

\[
\int u^r L(u) du = \begin{cases} 1 & \text{for } r = 0 \\ 0 & \text{for } 0 < r < q \\ c_r \in \mathbb{R} & \text{for } r \geq q \end{cases}.
\]

**A2:** Bandwidths satisfy \( m^{p+2} n^{-2(p+2)} \rightarrow \infty, \frac{q^2}{h^2} \rightarrow 0 \) and \( h = h_0 n^{-\delta}. \)

**A3:** The functions \( f_\alpha, f_{\alpha\beta} \) have bounded Lipschitz continuous \((p+1)^{th}\) derivatives.

**A4:** The variance function, \( \sigma^2(\cdot) \), is bounded and Lipschitz continuous.

**A5:** The \( d \)-dimensional density \( \varphi \) has compact support \( S_X \) with \( \inf_{x \in S_X} \varphi(x) > 0 \) and is Lipschitz continuous.

**Remark to assumption (A1):** Product kernels are chosen here for the ease of notation, especially in the proofs. The theorems work also for other multivariate kernels. In the following we will use the notation \( \|K\|_2^2 := \int K^2(x) dx \) for a kernel \( K \) (or \( K^* \)) of any dimension.

**Theorem 1** Let \( (x, \alpha, \beta) \) be in the interior of the support of \( \varphi_{\alpha\beta}(\cdot) \). Then under conditions (A1)-(A5),

\[
\sqrt{n} h^2 \left\{ \hat{f}_{\alpha\beta}(x, \alpha, \beta) - f_{\alpha\beta}(x, \alpha, \beta) - h^2 B_1(x, \alpha, \beta) \right\} \rightarrow^d N \left\{ 0, V_1(x, \alpha, \beta) \right\},
\]

where \( \hat{f}_{\alpha\beta} \) is given by (10) and

\[
V_1(x, \alpha, \beta) = \|K^*\|_2^2 \int \sigma^2(x) \frac{\varphi_{\alpha\beta}(x, \alpha, \beta)}{\varphi(x)} dx d\alpha d\beta.
\]

8
and

\[ B_1(x_\alpha, x_\beta) = \mu_2(K) \frac{1}{2} \left\{ f^{(2,0)}_{\alpha\beta}(x_\alpha, x_\beta) - \int f^{(2,0)}_{\alpha\beta}(x_\alpha, u_\beta) \varphi_{u_\beta}(u_\beta) du \right\}
+ f^{(0,2)}_{\alpha\beta}(x_\alpha, x_\beta) - \int f^{(0,2)}_{\alpha\beta}(u_\alpha, x_\beta) \varphi_{u_\alpha}(u_\alpha) du \}
\]

The proof of Theorem 1 is given in the appendix.

### 3.2 Estimation of derivatives

Since the estimation of derivatives for additive separable models has already been introduced in the paper of Severance-Lossin and Sperlich (1997), we concentrate in this section on estimating the mixed derivatives of the function \( F_{\alpha\beta} \). Although the derivative estimation for multivariate functions with the aid of multidimensional local polynomials is worked out in Ruppert and Wand (1994) and other papers, the case of mixed derivatives has not been explicitly considered yet. Our interest in this estimator is motivated by testing the hypothesis of additivity with no second order interaction. Since \( F^{(1,1)}_{\alpha\beta} = f^{(1,1)}_{\alpha\beta} \), to test for \( F^{(1,1)}_{\alpha\beta} \equiv 0 \) is equivalent to testing the hypothesis that \( f_{\alpha\beta} \) is zero.

Following the ideas of the previous section (or see also Severance-Lossin and Sperlich (1997)) at the pre-estimator point \((x_\alpha, x_\beta, X_{i\alpha\beta})\) we implement a special version of the local polynomial estimator. For our purpose it is enough to use a bivariate local polynomial estimator. We want to minimize

\[
\sum_{i=1}^n \left\{ Y_i - a_0 - a_1(X_{i\alpha} - x_\alpha) - a_2(X_{i\beta} - x_\beta) - a_3(X_{i\alpha} - x_\alpha)(X_{i\beta} - x_\beta) - a_4(X_{i\alpha} - x_\alpha)^2 \\
- a_5(X_{i\beta} - x_\beta)^2 \right\} K_h(X_{i\alpha} - x_\alpha) K_h(X_{i\beta} - x_\beta) L_g(X_{i\alpha\beta} - X_{i\alpha\beta})
\]

and accordingly define our estimator by

\[
\hat{F}^{(1,1)}_{\alpha\beta}(x_\alpha, x_\beta) = \frac{1}{n} \sum_{i=1}^n \varepsilon_{4,4}^{T} (Z_{\alpha\beta} W_{i,\alpha\beta} Z_{\alpha\beta})^{-1} Z_{\alpha\beta} W_{i,\alpha\beta} Y
\]

where \( Y, W_{i,\alpha\beta} \) are defined as above in Section 3.1 and \( \varepsilon_{4} = (0, 0, 0, 1, 0, 0) \).

Thus in equation (15) above, \( Z_{\alpha\beta} \) is

\[
Z_{\alpha\beta} = \begin{pmatrix}
1 & X_{1\alpha} - x_\alpha & X_{1\beta} - x_\beta & (X_{1\alpha} - x_\alpha)(X_{1\beta} - x_\beta) & (X_{1\alpha} - x_\alpha)^2 & (X_{1\beta} - x_\beta)^2 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
1 & X_{n\alpha} - x_\alpha & X_{n\beta} - x_\beta & (X_{n\alpha} - x_\alpha)(X_{n\beta} - x_\beta) & (X_{n\alpha} - x_\alpha)^2 & (X_{n\beta} - x_\beta)^2
\end{pmatrix}
\]

This estimator is bivariate locally quadratic for the directions \( \alpha \) and \( \beta \) and locally constant else. Certainly it is also possible to use polynomials of higher degree but for ease of presentation we restrict ourself to local quadratic polynomials.

Recalling the ideas of the preceding section we can now put the equivalent kernel \( K^* \) to effective use. Using a local quadratic smoother \( (p = 2) \) we have for the two dimensional case

\[
K^*_h(u, v) := K(u, v) s_2(1, u, v, u^2, v^2)^T
\]
where $s_\nu$ is the $(\nu + 1)^{th}$ row of

$$
S^{-1} = \begin{pmatrix}
\frac{\mu + \mu_2}{\mu - \mu_2} & 0 & 0 & 0 & \frac{1 - \mu_2}{\mu - \mu_2} & -\mu_2 \\
0 & \mu_2^{-1} & 0 & 0 & 0 & 0 \\
0 & 0 & \mu_2^{-1} & 0 & 0 & 0 \\
0 & 0 & 0 & \mu_2^{-2} & 0 & 0 \\
\frac{-\mu_2}{\mu_4 - \mu_2} & 0 & 0 & 0 & (\mu_4 - \mu_2)^{-1} & 0 \\
\frac{\mu + \mu_2}{\mu_4 - \mu_2} & 0 & 0 & 0 & 0 & (\mu_4 - \mu_2)^{-1}
\end{pmatrix}
$$

where $\mu_j = \mu_j(K) = \int u^j K(u)du$. The relationship between $S^{-1}$ and $(Z_{\alpha\beta}^T W_{1,\alpha\beta} Z_{\alpha\beta})^{-1}$ is given in Lemma A2 of the appendix.

If we want to estimate the mixed derivative, we use $K_3^*(u, v) = K(u, v)uv\mu_2^{-2}(K)$ where

$$
\int uv K_3^*(u, v) du dv = 1
$$

$$
\int u^q K_3^*(u, v) du dv = \int v^q K_3^*(u, v) du dv = 0 \quad \text{for} \ q = 0, 1, 2, 3, \ldots
$$

To state the asymptotics for the joint derivative estimator we need bandwidth conditions that differ slightly from (A2):

A6: Bandwidths satisfy $\frac{n^{3,3}}{h^2} \rightarrow \infty$, $\frac{\varphi^2}{h^2} \rightarrow 0$ and $h = h_0 n^{-\frac{1}{5}}$.

Then we have

**Theorem 2** Under conditions (A1), (A3)-(A6),

$$
\sqrt{n h^6} \left\{ \tilde{f}_{\alpha\beta}^{(1,1)}(x, \beta) - F_{\alpha\beta}^{(1,1)}(x, \beta) - h^2 B_1(x, \beta) \right\} \rightarrow \mathcal{N} \{ 0, V_2(x, \beta) \},
$$

where

$$
V_2(x, \beta) = ||K_3^*||_2^2 \int \sigma^2(x) \frac{\varphi_{\alpha\beta}^2(x, \beta)}{\varphi(x)} dx_{\alpha\beta}
$$

and

$$
B_1(x, \beta) = \mu_4(K)\mu_2^{-1}(K) \left[ \frac{1}{2} \left\{ f_{\alpha\beta}^{(2,1)}(x, \beta) \int \varphi_{\alpha\beta}^{(1,2)}(x, \beta) \int \varphi_{\alpha\beta} \right\} + \frac{1}{3!} \left\{ f_{\alpha\beta}^{(3,1)}(x, \beta) + f_{\alpha\beta}^{(1,3)}(x, \beta) + f_{\alpha\beta}^{(3,0)}(x, \beta) \right\} \int \varphi_{\alpha\beta} \right. \\
+ f_{\alpha}^{(3)}(x, \beta) \int \varphi_{\beta} + f_{\beta}^{(3)}(x, \beta) \int \varphi_{\alpha} + \sum_{\gamma \in D_{\alpha\beta}} \int f_{\alpha\gamma}^{(3)}(x, \alpha, \gamma) \varphi_{\beta} + \\
\left. \sum_{\gamma \in D_{\alpha\beta}} \int f_{\gamma\alpha}^{(3)}(\gamma, \alpha, \gamma) \varphi_{\beta} \right]
$$

with

$$
\varphi_{\alpha\beta} = \frac{\varphi_{\alpha\beta}(x, \beta)}{\varphi(x)} \frac{\partial \varphi(x)}{\partial x_{\alpha}} dx_{\alpha\beta}
$$

and $\varphi_{\beta}$ defined analogously.
4 Testing for Interaction

We are now in a position to state the problem of testing for second order interaction. As mentioned in Sections 1 and 2 for the model (3) we consider the null hypothesis $H_0 : f_{\alpha \beta} \equiv 0$, i.e. there is no interaction between $X_\alpha$ and $X_\beta$ for a fixed pair $(\alpha, \beta)$. Applying this test to any pair of different directions $X_\gamma$, $X_\delta$, $1 \leq \gamma < \delta \leq d$ this can be regarded as a test for additivity in the regression model.

In Section 2 we pointed out that for this purpose it is equivalent to consider $\tilde{f}_{\alpha \beta}$ instead of $f_{\alpha \beta}$. We propose two procedures; the first one is focused on $f_{\alpha \beta}$ directly, the second one on the mixed derivative $\tilde{f}^{(1,1)}_{\alpha \beta}$.

4.1 Considering the interaction function

We will briefly sketch the idea as to how the test statistic can be analysed and then state the theorem giving the asymptotics. The detailed proof is postponed to the appendix.

We consider $\tilde{\int} \tilde{f}_{\alpha \beta}(x_\alpha, x_\beta) \varphi_{\alpha \beta}(x_\alpha, x_\beta) dx_\alpha dx_\beta$. To study this test statistic, note first that by Theorem 1, equation (14) and some tedious calculations we get the following decomposition

$$\tilde{\int} \tilde{f}_{\alpha \beta}(x_\alpha, x_\beta) \varphi_{\alpha \beta}(x_\alpha, x_\beta) dx_\alpha dx_\beta = 2 \sum_{1 \leq i < j \leq n} H(X_i, \varepsilon_i, X_j, \varepsilon_j) + \sum_{i=1}^{n} H(X_i, \varepsilon_i, X_i, \varepsilon_i) +$$

$$\int \tilde{f}_{\alpha \beta}(x_\alpha, x_\beta) \varphi_{\alpha \beta}(x_\alpha, x_\beta) dx_\alpha dx_\beta + 2h^2 \int \tilde{f}_{\alpha \beta}(x_\alpha, x_\beta) B_1(x_\alpha, x_\beta) \varphi_{\alpha \beta}(x_\alpha, x_\beta) dx_\alpha dx_\beta + o(h^2)$$

where

$$H(X_i, \varepsilon_i, X_j, \varepsilon_j) = \varepsilon_i \varepsilon_j \int \frac{1}{n^2} (w_{ia} - w_{ia} - w_{ia} - w_{ia} - w_{ia} - w_{ia}) \sigma(X_i) \sigma(X_j) \varphi_{\alpha \beta}(x_\alpha, x_\beta) dx_\alpha dx_\beta$$

with weights $w_{ia}$, $w_{ia}$ and $w_{ia}$ defined in the appendix, equation (20) and (23).

We then calculate the asymptotics of $H(X_i, \varepsilon_i, X_j, \varepsilon_j)$ and $H(X_i, \varepsilon_i, X_j, \varepsilon_j)$, put the results together and obtain (cf. Lemma A3 of the appendix)

**Theorem 3** Under assumptions (A1) to (A5), as $h \to 0$ and $nh^2 \to \infty$

$$nh \tilde{\int} \tilde{f}_{\alpha \beta}(x_\alpha, x_\beta) \varphi_{\alpha \beta}(x_\alpha, x_\beta) dx_\alpha dx_\beta - \frac{2K^{(2)}(0)}{h} \int \varphi_{\alpha \beta}(z_{1:2}) \sigma^2(z) dz +$$

$$-nh \tilde{\int} \tilde{f}_{\alpha \beta}(x_\alpha, x_\beta) \varphi_{\alpha \beta}(x_\alpha, x_\beta) dx_\alpha dx_\beta - 2nh^3 \tilde{\int} \tilde{f}_{\alpha \beta}(x_\alpha, x_\beta) B_1(x_\alpha, x_\beta) \varphi_{\alpha \beta}(x_\alpha, x_\beta) dx_\alpha dx_\beta$$

$$\overset{N}{\sim} \frac{1}{2} K^{(2)} \left[ \int \frac{\varphi_{\alpha \beta}(z_{1:2})}{\varphi(z_{1:2})} - \frac{\varphi_{\alpha \beta}(z_{1:2})^2}{\varphi(z_{1:2})} \sigma^2(z) dz \right]$$

where $K^{(2)}$ is the 2-fold convolution of the kernel $K$, and where $B_1$ is defined in the formulation of Theorem 1.
4.2 Considering the mixed derivative of the joint influence

In contrast to the preceding method one can test for interaction without estimating the function of interaction \( f_{\alpha \beta} \) explicitly but looking at the mixed derivative of the function \( F_{\alpha \beta} \). Our test statistic is
\[
\int \bar{F}_{\alpha \beta}^{(1,1)} \varphi_{\alpha \beta}(x_\alpha, x_\beta) \, dx_\alpha \, dx_\beta
\]
which certainly for our purpose is the same as
\[
\int \bar{F}_{\alpha \beta}^{(1,1)} \varphi_{\alpha \beta}(x_\alpha, x_\beta) \, dx_\alpha \, dx_\beta.
\]
As can be seen from the proofs of Theorems 1 to 3, the asymptotics for this test statistic are the same as in Theorem 3 with the only difference that we now have to deal with \( K_3 \) and end up with asymptotic formulas containing \( K_1 \) instead of \( K_2 \); see the definition in Section 3.1. Thus we state the following theorem without an explicit proof.

**Theorem 4** Under assumptions (A1) and (A3)-(A6), as \( h \to 0 \) and \( nh^{s} \to \infty \)
\[
\frac{2}{h} \left( \frac{K_1^{(2)}(0)}{\varphi(z)} \right)^2 \int \varphi_{\alpha \beta}(z, \alpha, \beta) \varphi_{\alpha \beta}(z, \alpha, \beta) \sigma^2(z) \, dz
\]
\[
- \frac{2}{h} \int \bar{F}_{\alpha \beta}^{(1,1)} \varphi_{\alpha \beta}(x_\alpha, x_\beta) \, dx_\alpha \, dx_\beta
\]
\[
= N \left\{ 0, 8 \left\| K_1^{(2)} \right\|_2^4 \frac{\varphi_{\alpha \beta}(z_1, \alpha, \beta)}{\varphi(z_1)} \frac{\varphi_{\alpha \beta}(z_2, \alpha, \beta)}{\varphi(z_2)} \sigma^2(z_1) \sigma^2(z_2) \right\}
\]
where \( B_2 \) is defined in the formulation of Theorem 2.

5 An empirical investigation of the test procedures

In nonparametric statistics for small and moderate sample sizes one has to be careful when using the asymptotic distribution in practice. In our case we have the additional problem of having unknown expressions in the bias and variance of the test statistics, and we are dealing with a type of nonparametric test functional which has been known (Hjellvik, Yao and Tjøstheim (1998)) to possess a low degree of accuracy in its asymptotic distribution. It is therefore not unexpected when a simulation experiment (Section 5.2, Figure 2) for \( n = 150 \) observations reveals a very bad approximation for the asymptotics, and we must look for alternative ways to proceed for low and moderate sample sizes.

5.1 Using the wild bootstrap

One possible alternative is to use the bootstrap or the wild bootstrap, the latter being first introduced by Wu (1986) and Liu (1988). Härdle and Mammen (1993) set it into the context of nonparametric hypothesis testing as it will be used here.

The basic idea is to resample from residuals estimated under the null hypothesis by drawing each bootstrap residual from a two-point \( (a, b) \) distribution \( G_{(a,b),i} \) which has mean zero, variance equal
to the square of the residual and third moment equal to the cube of the residual for all \( i = 1, 2, \ldots, n \). Thus, through the use of one single observation one attempts to reconstruct the distribution for each residual separately up to the third moment. For this we do not need additional assumptions on \( \varepsilon \) or \( \sigma(\cdot) \).

Let \( T_n \) be the test statistic described in Theorem 3 or 4 and let \( n^* \) be the number of bootstrap replications. The whole procedure for the test using the wild bootstrap then consists of the following steps:

1. Estimate the regression function \( m_0 = m_{0,0,\beta} \) under the hypothesis \( H_{0,0,\beta} \) that \( f_{0,\beta} = f_{0,\beta} = 0 \) in model (3) for a fixed pair \( (\alpha, \beta) \), \( 1 \leq \alpha < \beta \leq d \) and construct the residuals \( \tilde{u}_i = \tilde{u}_{i,0,\beta} = Y_i - \tilde{m}_0(X_i) \), for \( i = 1, 2, \ldots, n \).

2. For each \( X_i \), randomly draw a bootstrap residual \( u_i^* \) from the distribution \( G_{(a,b),i} \) such that for \( U \sim G_{(a,b),i} \),

\[
E_G(a,b,i)(U) = 0, \quad E_G(a,b,i)(U^2) = \tilde{u}_i^2, \quad E_G(a,b,i)(U^3) = \tilde{u}_i^3.
\]

3. Generate a sample \( \{(Y_i^*, X_i)\}_{i=1}^{n^*} \) with \( Y_i^* = \tilde{m}_0 + u_i^* \). Here, for the estimation of \( m_0 \) it is recommended to use slightly oversmoothing bandwidths, see Härdle and Mammen (1993).

4. Calculate the bootstrap test statistic \( T_{n^*} \) using the sample \( \{(Y_i^*, X_i)\}_{i=1}^{n^*} \) in the same way as the original \( T_n \) is calculated.

5. Repeat steps 2-4 \( n^* \) times and use the \( n^* \) different \( T_{n^*} \) to determine the quantiles of the test statistic under the null hypothesis and subsequently the critical value for the rejection boundaries.

For the two-point distribution \( G_{(a,b),i} \): we have used the so called golden cut method, setting \( G_{(a,b),i} = q\delta_a + (1-q)\delta_b \) where \( \delta_a, \delta_b \) denote point measures at \( a = \tilde{u}_i(1 - \sqrt{5})/2, b = \tilde{u}_i(1 + \sqrt{5})/2 \) with \( q \) has to be \( (5 + \sqrt{5})/10 \).

For the marginal integration estimator Dalelane (1998) recently proved that the wild bootstrap works for the case of i.i.d. observations. In the setting of times series some work on this has been done by Achmus (1998). Dalelane showed via strong approximation that it holds in supremum norm whereas Achmus proved that the wild bootstrap holds at least locally for time series. There is still some work needed to establish a theory of the wild bootstrap for the test statistic we are using. But this is beyond the scope of the paper.

### 5.2 The simulation study

To compare our two test procedures, to investigate and demonstrate their behavior empirically as well as to present how well the estimation works we did a simulation study for a small sample size.
of \( n = 150 \) observations. The data have been generated from the model

\[
m(x) = E(Y|X = x) = c + \sum_{j=1}^{3} f_j(x_j) + f_{1,2}(x_1, x_2)
\]

where

\[
\begin{align*}
f_1(u) &= 2u \\
f_2(u) &= 1.5 \sin(-1.5u) \\
f_3(u) &= -u^2 + E(u^2)
\end{align*}
\]

and

\[
f_{1,2}(u, v) = auv
\]

with \( a = 0 \) under the null hypothesis and \( a = 1 \) under the alternative. The input variables \( X_j, j = 1, 2, 3 \) are i.i.d. uniform on \([-2, 2]\). To generate the response \( Y \) we added normally distributed error terms with standard deviation \( \sigma = 0.5 \) to the regression function \( m(x) \).

For calculating the test statistic we used the quartic kernel \( \frac{15}{16}(1 - u^2)^2 \mathbb{1}[|u| \leq 1] \) for \( K(u) \) and \( L(u) \) and product kernels for higher dimensions. We chose different bandwidths depending on the testing procedure and whether the direction was of interest or not (in the previous sections we distinguished them by denoting them \( h \) and \( g \)).

When we considered the test statistic based on the estimation of \( \hat{f}_{1,2} \) (direct test) we used \( h = 0.9, g = 1.1 \) and for the pre-estimation to do the wild bootstrap \( h = 1.0 \) and \( g = 1.2 \). To calculate the test statistic based on the joint derivative \( f_{1,2}^{(1,1)} \) (testing derivatives) we selected \( h = 1.5, g = 1.6 \) and \( h = 1.4, g = 1.5 \), respectively.

In Figure 1 we depict the performance of the estimation procedure for \( a = 1.0 \) in (17) using the local linear smoother. The estimates of \( f_1, f_2 \) and \( f_3 \) with their corresponding true functions are displayed in the upper part of Figure 1; the corresponding estimate \( \hat{f}_{1,2} \) in the lower part. The estimation procedure is working quite well.

Turning to testing, we consider the null hypothesis \( H_0 : \ f_{1,2}(u) \equiv 0 \). First we take a look at the asymptotics. In Figure 2 we have plotted kernel estimates of the standardized densities of the test procedures compared to the standard normal distribution. The densities of the test statistics have been estimated with a quartic kernel and bandwidth 0.2. To make the densities comparable we also smoothed the normal densities using the same kernel. We see clearly that the test statistics we introduced in the previous sections look more like a \( \chi^2 \) distributed random variable than a normal one. Thus, even if we could estimate bias and variance of the test statistics well, the asymptotic distribution of them is hardly usable for testing for such a moderate sample of observations.

This conclusion is consistent with the results of Hjellvik, Yao and Tjøstheim (1998) for a similar type of functional designed for testing of linearity. For that functional roughly 100000 observations were needed to obtain a good approximation. The reason is that for a functional of the type \( \int \int \beta(x, x) \pi(x, x) dx dx \) several of the leading terms of the Edgeworth expansion are nearly of the same magnitude, so that very many observations are needed for the dominance of the first order term yielding normality. We refer to Hjellvik, Yao and Tjøstheim (1998) for more details.
Figure 1: Additive components (dashed) and their estimates (solid), $f_1$ (top), $f_2$ (upper left), $f_3$ (upper right) and $\tilde{f}_{1,2}$ (lower).

To get the results of Table 1 and Figure 3, describing the bootstrap version of the tests, we did 249...
Figure 2: Densities of the test statistics; direct method (solid), testing derivatives (dashed) and normal density (thick, solid).

bootstrap replications and considered the test statistics

\[
\frac{1}{n} \sum_{i=1}^{n} \tilde{f}_{1,2}(X_1, X_2) \mathbb{I} \{|X_k| \leq 1.6 \text{ for } k = 1, 2\}
\]

and

\[
\frac{1}{n} \sum_{i=1}^{n} f_{1,2}^{[1,1]}(X_1, X_2) \mathbb{I} \{|X_k| \leq 1.6 \text{ for } k = 1, 2\}
\]

respectively, i.e., we used a weight function for the test statistic to correct for boundary effects caused by the estimation.

Table 1 is presenting the error of the first kind for both methods and at different significance levels.

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>significance level in %</td>
</tr>
<tr>
<td>direct method</td>
</tr>
<tr>
<td>testing derivatives</td>
</tr>
</tbody>
</table>

For both test procedures obtaining an accurate error of the first kind with the aid of wild bootstrap depends on a proper choice of bandwidth. Thus, Table 1 does not give decisive information whether the direct testing procedure is superior to the other one. We just see that wild bootstrap obviously works quite well and can be used for this test problem. For a comparison of the direct method against the derivative approach and to be able to judge the tests more generally we have to look at
the power at a wide range of examples. The power as a function of \( a \) in (17) is displayed for both methods and different levels in Figure 3. Both procedures are working well. For this particular model the power function of the direct method is steeper, but it is quite likely that the comparative advantages of the two methods depend on the particular model or design.

5.3 An Application to Production Function Estimation

In this section we use our estimation and testing procedures for a five dimensional production function.

Separability and additivity of production functions have been discussed since the early paper by Leontief (1947). These conditions yield many important economic results, e.g. they allow the aggregation of inputs or decentralization in decision-making. But there has been much discussion in the past whether production functions can be taken to be additive (strongly separable \(^2\)) for a particular data set. This discussion goes back at least to Denny and Fuss (1977), Fuss, McFadden

---

\(^2\)The expression "strong separability" is equivalently used for "additivity" or "generalized additivity", see Berndt and Christensen (1973).
and Mundlak (1978), Deaton and Muellbauer (1980, pp.117-165). Our test procedure is an adequate tool to investigate the hypothesis of additivity.

We consider the example and data of Severance-Lossin and Sperlich (1997) and look at the estimation of a production function for livestock in Wisconsin. In that paper strong separability (additivity) among the input factors was assumed and the additive components and their derivatives were estimated using the marginal integration estimator. Whereas their interest was focused mainly on the return to scale and thus on the derivative estimation, we are more interested in examining the validity of the assumption of additivity by looking at the second order interaction terms. We use a subset of $n = 250$ observations of an original data set of more than 1000 Wisconsin farms collected by the Farm Credit Service of St. Paul, Minnesota in 1987. Severance-Lossin and Sperlich removed outliers and incomplete records and selected farms which only produced animal outputs. The data consists of farm level inputs and outputs measured in dollars. The output $Y$ in this analysis is livestock, the input variables are family labor $X_1$, hired labor $X_2$, miscellaneous inputs (e.g. repairs, rent, custom hiring, supplies, insurance, gas, oil, and utilities) $X_3$, animal inputs (purchased feed, breeding, and veterinary services) $X_4$, and intermediate run assets (assets with a useful life of one to ten years) $X_5$.

The underlying additive model is of the form

$$
\ln (y) = c + \sum_{a=1}^{d} f_a \{\ln(x_a)\}.
$$

This model can be viewed as a generalization of the Cobb-Douglas production technology. In the Cobb-Douglas model we would have $f_a \{\ln(x_a)\} = \beta_a \ln(x_a)$.

We have extended this model by including interaction terms $f_{a\beta}$ to obtain

$$
\ln (y) = c + \sum_{a=1}^{d} f_a \{\ln(x_a)\} + \sum_{1 \leq a < \beta \leq d} f_{a\beta} \{\ln(x_a), \ln(x_\beta)\}
$$

and the assumed strong separability (additivity) can be checked by testing the null hypothesis $H_0: f_{a\beta} \equiv 0$ for all $a, \beta$.

First we estimated all functions $f_a$ and $f_{a\beta}$. The estimation results are given in Figures 4 to 6. For the estimation we used the quartic kernel for $K$ and $L$. The data were divided by their standard deviations so that we could choose the same bandwidths for each direction. We tried different bandwidths and $h = 1.7$ and $g = 3.3$ yield reasonable smooth estimates. However, we know by experience that the integration estimator is quite robust against different choices of bandwidths. For a detailed discussion of the bandwidth choice and robustness, compare Sperlich, Linton and Härdle (1997).

In Figure 4 the univariate function estimates (not centered to zero) are displayed together with a kind of partial residuals $\hat{r}_{ia} := y_i - \sum_{j \neq a} f_{ij}(X_{ij}) = f_{i\alpha}(X_{i\alpha}) + \varepsilon_i$. To see clearly the shape of the estimates we display the main part of the point clouds including the function estimates. As mentioned already in Severance-Lossin and Sperlich, the graphs in Figure 4 give some indication of nonlinearity in family labor, hired labor and intermediate run assets. They even seem to indicate
that the elasticities for these inputs increase and finally could lead to increasing returns to scale. An obvious inference from the economic point of view would be that larger farms are more productive.

Figure 4: Function estimates for the univariate additive components and partial residuals.

In Figures 5 and 6 we have shown the estimates of the bivariate interaction terms $f_{\alpha\beta}$. For their estimation and presentation we trimmed the data by removing 2% of the most extreme data points. The interaction terms seem not to provide an (economic) interpretation.
Figure 5: Estimates of the interaction terms.
Figure 6: Estimates of the interaction terms.

For the testing we again used the quartic kernel and trimmed the data by removing 2% at the tails. We did 249 bootstrap replications.

Since we know about the sensitivity of the test procedures against the choice of bandwidths, we applied the procedures for a wide range of different bandwidths. For the first method, which employs the estimate of the interaction term directly, we used $h = 1.3$ to $2.1$, $g = 2.9$ to $3.7$ for the pre-estimation to get estimates for the bootstrap and $h = 1.6$ to $2.4$, $g = 3.1$ to $3.9$ to calculate the test statistics. For the second method which involves the mixed derivatives of the interaction term, we used $h = 1.6$ to $2.4$, $g = 3.1$ to $3.9$ for the pre-estimation to get estimates for the bootstrap and $h = 2.1$ to $2.9$, $g = 3.1$ to $3.9$ to calculate the test statistics.

To test the different interaction terms for significance, we used the following iterative model selection procedure. First we calculated the p-values for each interaction term $f_{\alpha\beta}$ including all the other functions in the model (19). Then we removed the function $f_{\alpha\beta}$ with the highest p-value, and again determined the p-values for the remaining interaction terms as above. Stepwise dropping out the interaction terms with the highest p-value, we end up with the most significant ones.

This procedure was applied for both testing methods. For large bandwidths the interactions are smoothed out and we never rejected the null hypothesis of no interaction for any of the pairwise terms, but for small bandwidths some of the interactions terms turned out to be significant. For the first method, where we consider the interaction terms directly, the term $f_{1,3}$ (family labor and miscellaneous inputs) was significant at a 5% level with a p-value of about 2%. Of the other terms $f_{1,3}$ and $f_{1,5}$ came closest to being significant.
For the second method, considering the derivatives, $f_{1,5}$ (family labor and intermediate run assets) and $f_{3,5}$ (miscellaneous inputs and intermediate run assets) had the lowest p-values, $f_{1,5}$ having a p-value of less than 1%.

Even though the two procedures are not entirely consistent in their selection of relevant interaction terms, both procedures indicate that a weak form of interaction is present, and that the variable "family labor plays a significant role in the interaction. There are fairly clear indications from Figure 5 that $f_{1,3}$ and $f_{1,5}$ are not multiplicative in their input factors. This would make it difficult for a parametric test to detect the interaction.

A Appendix

A.1 Proof of Theorem 1

The proof of Theorem 1 makes use of the following lemmas, whose proofs are not difficult. They can be found in Severance-Lossin and Sperlich (1997).

Lemma A1 Let $D_n$, $B_n$ and $A$ be matrices, possibly having random variables as their entries. Further, let $D_n = A + B_n$ where $A^{-1}$ exists and $B_n = (b_{ij})_{1 \leq i, j \leq d}$ where $b_{ij} = O_p(\delta_n)$ with $d$ fixed, independent of $n$. Then $D^{-1}_n = A^{-1}(I + C_n)$ where $C_n = (c_{ij})_{1 \leq i, j \leq d}$ and $c_{ij} = O_p(\delta_n)$. Here $\delta_n$ denotes a function of $n$, going to zero with increasing $n$.

Lemma A2 Let $W_{i, a}, W_{i, a\beta}, Z_a, Z_{a\beta}$ and $S$ be defined as in Section 3.1 and $H = diag(h^{-1})_{i=1, \ldots, g+1}$. Then

\begin{align*}
\text{a)} \quad (H^{-1}Z_\alpha^T W_{i, a} Z_a H^{-1})^{-1} &= \frac{1}{\varphi(x_{\alpha, a}, \lambda)} s^{-1}\left\{ I + O_p \left( h + \frac{\ln n}{\sqrt{nh_\beta}} \right) \right\} \\
\text{and} \quad (H^{-1}Z_{a\beta}^T W_{i, a\beta} Z_{a\beta} H^{-1})^{-1} &= \frac{1}{\varphi(x_{a\beta, a\beta}, \lambda_{a\beta})} s^{-1}\left\{ I + O_p \left( h + \frac{\ln n}{\sqrt{nh_\beta}} \right) \right\}.
\end{align*}

Define $E_x[.] = E[\cdot | X_{i1}, \ldots, X_{id}]$ and $E_x[.] = E[\cdot | X]$, where $X$ is the design matrix \{ $X_{i\alpha}$ \} _{i, \alpha = 1, 1}^{n, d}$.

The proof of Theorem 1 can now be divided into two parts:

I) We start by considering the univariate estimator $\hat{F}_n$. This is one component of the estimator $\tilde{f}_{a\beta}$ of interest in Theorem 1. First we will separate the difference between the estimator and the true function into a bias and a variance part.

Defining the vector
\( F_t = \left( c + f_\alpha(x_\alpha) + \sum_{\gamma \in D_\alpha} f_{\alpha\gamma}(x_\alpha, X_{i\gamma}) + \sum_{\gamma \in D_\alpha} f_\gamma(X_{i\gamma}) + \sum_{(\gamma, \delta) \in D_{\alpha\alpha}} f_{\gamma\delta}(X_{i\gamma}, X_{i\delta}) \right) \)

and applying Lemma A.2, we have

\[
\hat{F}_\alpha(x_\alpha) - F_\alpha(x_\alpha) \\
= \frac{1}{n} \sum_{i=1}^{n} \left( Z^T_{\alpha} W_{i,\alpha} Z_{\alpha} \right)^{-1} Z^T_{\alpha} W_{i,\alpha} Y - F_\alpha(x_\alpha) \\
= \frac{1}{n} \sum_{i=1}^{n} \left( Z^T_{\alpha} W_{i,\alpha} Z_{\alpha} \right)^{-1} Z^T_{\alpha} W_{i,\alpha} (Y - Z_\alpha F_i) + O_p(n^{-1/2}) \\
= \frac{1}{n} \sum_{i=1}^{n} \varphi(x_\alpha, X_{i\alpha}) \epsilon_1 S^{-1} \left( I + O_p \left( h + \frac{\ln n}{\sqrt{n h g^{d-1}}} \right) \right) H^{-1} Z^T_{\alpha} W_{i,\alpha} (Y - Z_\alpha F_i) + O_p(n^{-1/2})
\]

When we compute the matrix product and use for \( Y_i = \sigma(X_i) \epsilon_i + m(X_i) \) the Taylor expansion of \( m(X_i) \) around \( (x_\alpha, X_{i\alpha}) \) we get

\[
\hat{F}_\alpha(x_\alpha) - F_\alpha(x_\alpha) \\
= \frac{1}{n} \sum_{i=1}^{n} \varphi(x_\alpha, X_{i\alpha}) \frac{1}{n} \sum_{i=1}^{n} K_h (X_{i\alpha} - x_\alpha) L_2 (X_{i\alpha} - X_{i\alpha}) \left( 1 + O_p \left( h + \frac{\ln n}{\sqrt{n h g^{d-1}}} \right) \right) \times \\
\left[ \frac{(X_{i\alpha} - x_\alpha)}{2} \right] \left\{ f^{(2)}_\alpha(x_\alpha) + \sum_{\gamma \in D_\alpha} f^{(2,0)}_{\alpha\gamma}(x_\alpha, X_{i\gamma}) \right\} + \sum_{\gamma \in D_\alpha} \left\{ f_\gamma(X_{i\gamma}) - f_\gamma(X_{i\gamma}) \right\} + \\
\sum_{(\gamma, \delta) \in D_{\alpha\alpha}} \left\{ f_{\gamma\delta}(X_{i\gamma}, X_{i\delta}) - f_{\gamma\delta}(X_{i\gamma}, X_{i\delta}) \right\} + O_p \{(X_{i\alpha} - x_\alpha)^3 + \sigma(X_i) \epsilon_i \} + O_p(n^{-1/2})
\]

Now we can separate this expression into a systematic "bias" and a stochastic "variance". Then we have

\[
\hat{F}_\alpha(x_\alpha) - F_\alpha(x_\alpha) = \frac{1}{n} \sum_{i=1}^{n} E_i(\tilde{a}_i) \frac{1}{n} \sum_{i=1}^{n} \tilde{a}_i - E_i(\tilde{a}_i) + O_p \left( \frac{h}{\sqrt{n h g^{d-1}}} + \frac{\ln n}{n h g^{d-1}} \right)
\]

where,

\[
\tilde{a}_i = \frac{1}{n} \sum_{i=1}^{n} K_h (X_{i\alpha} - x_\alpha) L_2 (X_{i\alpha} - X_{i\alpha}) \times [\ldots]
\]

and the expression in the brackets \([\ldots]\) is as in the formula above. Notice that \( \tilde{a}_i \) is \( O_p \{ (n h g^{d-1})^{-1/2} \} \).

It remains to work with the first order approximations.

Let

\[
T_{1n} = \frac{1}{n} \sum_{i=1}^{n} \frac{E_i(\tilde{a}_i)}{\varphi(x_\alpha, X_{i\alpha})}; \quad T_{2n} = \frac{1}{n} \sum_{i=1}^{n} \frac{\tilde{a}_i - E_i(\tilde{a}_i)}{\varphi(x_\alpha, X_{i\alpha})};
\]

23
For the bias part we prove that
\[
T_{1n} = h^2 \mu_2 (K) \left\{ \frac{1}{2} \left( f^{(2)}_\alpha (x_\alpha) + \sum_{\gamma \in D_\alpha} \frac{1}{n} \sum_{i=1}^n f^{(2,0)}_{\alpha \gamma} (x_\alpha, X_{i\gamma}) \right) \right\} + o_p(h^2).
\]

Consider \( \varphi(x_\alpha, X_{i\alpha})^{-1} E_i(\tilde{a}_i) \), which is, in fact, an approximation of the (conditional) bias of the Nadaraya-Watson estimator at \((x_\alpha, X_{i\alpha})\). This is, by assumptions (A1), (A2), (A3) and (A5)

\[
\begin{align*}
\frac{E_i(\tilde{a}_i)}{\varphi(x_\alpha, X_{i\alpha})} & = \frac{1}{\varphi(x_\alpha, X_{i\alpha})} \int K_h(z - x_\alpha) \varphi(z, w) \times \\
& \left\{ \frac{1}{2} \left( f^{(2)}_\alpha (x_\alpha) + \sum_{\gamma \in D_\alpha} f^{(2,0)}_{\alpha \gamma} (x_\alpha, X_{i\gamma}) \right) + \sum_{\gamma \in D_\alpha} \left\{ f_\gamma (X_{i\gamma} - f_\gamma (X_{i\gamma})) \right\} + \\
& \sum_{(\gamma, \ell) \in D_{\alpha \alpha}} \left\{ f_\gamma (X_{i\gamma}, X_{i\ell}) - f_\gamma (X_{i\gamma}, X_{i\ell}) \right\} + O_p((z - x_\alpha)^3) \right\} dwdz + o_p(1)
\end{align*}
\]

since \( E_\epsilon(x_\epsilon) = 0 \), respectively \( E_i(\epsilon_i) = 0 \) for all \( i \) and \( l \). We have used here the substitutions \( u = \frac{z - x_\alpha}{h} \) and \( v = \frac{w - X_{i\alpha}}{g} \), where \( v \) and \( w \) are \((d - 1)\)-dimensional vectors with \( \gamma^{th} \) component \( v_\gamma \), respectively \( w_\gamma \).

Since the random variables \( \varphi(x_\alpha, X_{i\alpha})^{-1} E_i(\tilde{a}_i) \) are bounded we have using (A2)

\[
T_{1n} = h^2 \mu_2 (K) \left\{ \frac{1}{2} \left( f^{(2)}_\alpha (x_\alpha) + \sum_{\gamma \in D_\alpha} \frac{1}{n} \sum_{i=1}^n f^{(2,0)}_{\alpha \gamma} (x_\alpha, X_{i\gamma}) \right) \right\} + o_p(h^2)
\]
For the stochastic term we use the same technique as in Severance-Lossin and Sperlich (1997) to prove that

\( w_{io} = \frac{1}{n} K_h(x_o - X_{io}) \frac{\varphi(x_o, X_{io})}{\varphi(x_o, X_{io})} \).

\[ w_{io} \sigma(X_{i}) \varepsilon_{i} + o_{p}\left\{ (nh)^{-1/2}\right\} . \]

with a rate of \( \sqrt{nh} \).

II) Analogous to the univariate case of \( \hat{F}_a \), we proceed for the bivariate case considering \( \hat{F}_{a\beta} \):

We need the following definition

\[
F_i = \left( c + f_a(x_a) + f_{\beta}(x_\beta) + f_{a\beta}(x_a, x_\beta) + \sum_{\gamma \in D_{a,\beta}} \{ \ldots \} \right)\\
= \left( f_a^{(1)}(x_a) + \sum_{\gamma \in D_{a,\beta}} f_{a,\gamma}^{(1)}(x_a, X_{i\gamma}) + f_{a\beta}^{(0)}(x_a, x_\beta) \right)\\
= \left( f_{\beta}^{(1)}(x_\beta) + \sum_{\gamma \in D_{a,\beta}} f_{\beta,\gamma}^{(1)}(x_\beta, X_{i\gamma}) + f_{a\beta}^{(0)}(x_a, x_\beta) \right),
\]

where \{\ldots\} is

\[
\left\{ f_{a\gamma}(x_a, X_{i\gamma}) + f_{\beta\gamma}(x_\beta, X_{i\gamma}) + f_{\gamma}(X_{i\gamma}) + \sum_{\gamma, i \in D_{a,\beta}} f_{\gamma i}(X_{i\gamma}, x_i) \right\}.
\]

Applying Lemma A2 b) we have for the estimator

\[
\hat{F}_{a\beta}(x_a, x_\beta) - F_{a\beta}(x_a, x_\beta) = \frac{1}{n} \sum_{i=1}^{n} \epsilon_i \left( Z_{a\beta} W_{i,a\beta} Z_{a\beta} \right)^{-1} Z_{a\beta} W_{i,a\beta} Y - F_{a\beta}(x_a, x_\beta)\\
= \frac{1}{n} \sum_{i=1}^{n} \epsilon_i \left( Z_{a\beta} W_{i,a\beta} Z_{a\beta} \right)^{-1} Z_{a\beta} W_{i,a\beta} (Y - Z_{a\beta} F_{i}) + O_p(n^{-\frac{1}{2}})\\
= \frac{1}{n} \sum_{i=1}^{n} \frac{1}{\varphi(x_a, x_\beta, X_{i\alpha\beta})} \epsilon_i S^{-1} \left\{ I + O_p \left( h + \frac{\ln n}{\sqrt{nh^2g^2-1}} \right) \right\}\\
\times H^{-1} Z_{a\beta} W_{i,a\beta} (Y - Z_{a\beta} F_{i}) + O_p(n^{-\frac{1}{2}}).
\]

As above in I) we do the matrix calculation, replace \( Y_i \) by \( Y_i = \sigma(X_i) \varepsilon_i + m(X_i) \), and use the Taylor expansion of \( m \) around \( (x_a, x_\beta, X_{i\alpha\beta}) \). Then we get

\[
\hat{F}_{a\beta}(x_a, x_\beta) = F_{a\beta}(x_a, x_\beta) + \frac{1}{n} \sum_{i=1}^{n} \varphi(x_a, x_\beta, X_{i\alpha\beta}) \frac{1}{n} \sum_{i=1}^{n} K_h(X_{i\alpha} - x_a) K_h(X_{i\beta} - x_\beta) L_g \left( X_{i\alpha\beta} - X_{i\alpha\beta} \right) \times\\
\left\{ I + O_p \left( h + \frac{\ln n}{\sqrt{nh^2g^2-1}} \right) \right\} \left[ \frac{(X_{i\alpha} - x_a)^2}{2} \{ f_a^{(2)}(x_a) + \sum_{\gamma \in D_{a,\beta}} f_{\gamma i}^{(2)}(x_a, x_i) \} \right].
\]

25
Consider Nadaraya-Watson estimator at $x_i$. We pursue the same steps as for the one dimensional case and separate this expression into a systematic "bias" and a stochastic "variance":

$$
+ f^{(2)}_{\alpha \beta}(x_i, x_j) \left\{ f^{(2)}_{\beta}(x_i) + \sum_{\gamma \in D_{a,\beta}} f^{(2,0)}_{\beta \gamma}(x_i, X_\gamma) \right\} + \sum_{\gamma \in D_{a,\beta}} \sum_{(\gamma, \ell) \in D_{a,\beta}} \left\{ f^{(1)}_{\gamma \ell}(X_\gamma, X_\ell) \right\} + \sum_{(\gamma, \ell) \in D_{a,\beta}} f^{(1)}_{\gamma \ell}(X_\gamma, X_\ell)$$

where

$$
\hat{a}_i = \frac{1}{n} \sum_{i=1}^{n} K_h(X_{i_0} - x_0) K_h(X_{i_2} - x_2) L_x(X_{i_0} - X_{i_2}) \times \left[ \ldots \right]
$$

and $[\ldots]$ is the expression in the same angular brackets of equation (22). Notice that $\hat{a}_i$ is $O_p\left\{ (nh^2g^{d-2})^{-1/2} \right\}$.

Again we only have to work with the first order approximations. Let

$$
T_1 = \frac{1}{n} \sum_{i=1}^{n} \frac{E_i(\hat{a}_i)}{\varphi(x_0, x_2, X_{i_0})} ; \quad T_2 = \frac{1}{n} \sum_{i=1}^{n} \frac{\hat{a}_i - E_i(\hat{a}_i)}{\varphi(x_0, x_2, X_{i_0})}.
$$

We prove:

$$
T_1 = h^2 \mu_2(K) \frac{1}{2} \left\{ f^{(2)}_{\alpha \beta}(x) + \sum_{\gamma \in D_{a,\beta}} \frac{1}{n} \sum_{i=1}^{n} f^{(2,0)}_{\alpha \beta \gamma}(x, X_\gamma) + f^{(2)}_{\beta}(x_\beta) + \sum_{\gamma \in D_{a,\beta}} \sum_{(\gamma, \ell) \in D_{a,\beta}} f^{(2,0)}_{\beta \gamma}(x_\gamma, X_\ell) + f^{(1)}_{\alpha \beta \gamma}(x_\gamma, x_\beta) + f^{(2)}_{\alpha \beta \gamma}(x_\gamma, x_\beta) \right\} + o_p(h^2)
$$

Consider $\varphi(x_0, x_2, X_{i_0})^{-1} E_i(\hat{a}_i)$, which is again an approximation of the (conditional) bias of the Nadaraya-Watson estimator at $(x_0, x_2, X_{i_0})$. By assumptions (A1), (A2), (A3) and (A5) we have

$$
\frac{E_i(\hat{a}_i)}{\varphi(x_0, x_2, X_{i_0})} = \frac{1}{\varphi(x_0, x_2, X_{i_0})} \int K_h(z_0 - x_0) K_h(z_2 - x_2) L_x(w - X_{i_0}) \varphi(z, w) \left[ \frac{(z_0 - x_0)^2}{2} \left\{ f^{(2)}_{\alpha \beta}(x) + \sum_{\gamma \in D_{a,\beta}} f^{(2,0)}_{\alpha \beta \gamma}(x, X_\gamma) + f^{(2)}_{\beta}(x_\beta) \right\} + \right]
$$
\[
\frac{(z_\beta - x_\beta)^2}{2} \left\{ f_\beta^{(2)}(x_\beta) + \sum_{\gamma \in D_{n,\beta}} f^{(1,0)}_{\beta\gamma}(x_\beta, X_{i\gamma}) + f^{(0,2)}_{\alpha\beta}(x_\alpha, x_\beta) \right\} + \\
\sum_{\gamma \in D_{n,\beta}} \left\{ f_\gamma(w_\gamma) - f_\gamma(X_{i\gamma}) \right\} + \sum_{\gamma, i \in D_{n,\beta}} \left\{ f_\gamma(w_\gamma, w_i) - f_\gamma(X_{i\gamma}, X_{i\bar{\gamma}}) \right\} + \\
(z_\alpha - x_\alpha)(z_\beta - x_\beta) f^{(1,1)}_{\alpha\beta}(x_\alpha, x_\beta) + O_p\left\{ (z_\alpha - x_\alpha)^3 \right\} + O_p\left\{ (z_\beta - x_\beta)^3 \right\} + \\
o_p\left\{ (z_\alpha - x_\alpha)(z_\beta - x_\beta) \right\} \right] dw dz + o_p(1) \\
= \frac{1}{\varphi(x_\alpha, x_\beta, X_{i\alpha\beta})} \int K(u_\alpha) K(u_\beta) L(w) \varphi(x_\alpha + u_\alpha h, x_\beta + u_\beta h, X_{i\alpha\beta} + \nu g) \times \\
\left[ \frac{(hu_\alpha)^2}{2} \left\{ f^{(2)}_\alpha(x_\alpha) + \sum_{\gamma \in D_{n,\beta}} f^{(2,0)}_{\alpha\gamma}(x_\alpha, X_{i\gamma}) + f^{(2)}_{\beta}(x_\beta) \right\} + \frac{(hu_\beta)^2}{2} \right. \\
\left\{ f^{(2)}_\beta(x_\beta) + \sum_{\gamma \in D_{n,\beta}} f^{(2,0)}_{\beta\gamma}(x_\beta, X_{i\gamma}) + f^{(0,1)}_{\alpha\beta}(x_\alpha, x_\beta) \right\} + \sum_{\gamma \in D_{n,\beta}} \left\{ f_\gamma(X_{i\gamma} + g v_\gamma) - f_\gamma(X_{i\gamma}) \right\} + \\
\left. \left\{ f_\gamma(X_{i\gamma}) \right\} + \sum_{(\gamma, i) \in D_{n,\beta}} \left\{ f_\gamma(w_\gamma, X_{i\beta} + g v_\gamma) - f_\gamma(X_{i\gamma}, X_{i\bar{\gamma}}) \right\} + \sum_{(\gamma, i) \in D_{n,\beta}} \left\{ f_\gamma(w_\gamma, X_{i\beta}) \right\} \right] dw du + o_p(1) \\
= h^2 \mu_2(K) \left\{ \frac{1}{2} \left\{ f^{(2)}_\alpha(x_\alpha) + \sum_{\gamma \in D_{n,\beta}} f^{(2,0)}_{\alpha\gamma}(x_\alpha, X_{i\gamma}) + f^{(2)}_{\beta}(x_\beta) \right\} + \sum_{\gamma \in D_{n,\beta}} f^{(2,0)}_{\beta\gamma}(x_\beta, X_{i\gamma}) + f^{(1,0)}_{\alpha\beta}(x_\alpha, x_\beta) + f^{(0,2)}_{\alpha\beta}(x_\alpha, x_\beta) \right\} + o_p(h^2) + O_p(g^2)
\]

since \( E_\epsilon [\epsilon_i] = 0 \). We have used here the substitutions \( u = \frac{z - (x_\alpha, x_\beta)^T}{h} \) and \( v = \frac{w - X_{i\alpha\beta}}{g} \), where \( v, w \) are \((d - 2)\)-dimensional vectors with \( \gamma^{th} \) component \( \nu_\gamma \), \( w_\gamma \).

Since the \( \varphi(x_\alpha, x_\beta, X_{i\alpha\beta})^{-1} E_\epsilon(\bar{\epsilon}_i) \) are independent and bounded we have

\[
T_{2n} = h^2 \mu_2(K) \left\{ \frac{1}{2} \left\{ f^{(2)}_\alpha(x_\alpha) + \sum_{\gamma \in D_{n,\beta}} \frac{1}{n} \sum_{i=1}^n f^{(2,0)}_{\alpha\gamma}(x_\alpha, X_{i\gamma}) + f^{(2)}_{\beta}(x_\beta) \right\} + \sum_{\gamma \in D_{n,\beta}} \frac{1}{n} \sum_{i=1}^n f^{(2,0)}_{\beta\gamma}(x_\beta, X_{i\gamma}) + f^{(1,0)}_{\alpha\beta}(x_\alpha, x_\beta) + f^{(0,2)}_{\alpha\beta}(x_\alpha, x_\beta) \right\} + o_p(h^2)
\]

Thus, combining with the bias formulas obtained for \( \hat{F}_\alpha(x_\alpha) \) and \( \hat{F}_\beta(x_\beta) \), the bias of \( \hat{F}_{\alpha\beta}(x_\alpha, x_\beta) - \hat{F}_\alpha(x_\alpha) - \hat{F}_\beta(x_\beta) \) is as claimed in Theorem 1

\[
h^2 B_1 = h^2 \mu_2(K) \left\{ \frac{1}{2} \left\{ f^{(2)}_{\alpha\beta}(x_\alpha, x_\beta) - \int f^{(2,0)}_{\alpha\beta}(x_\alpha, u_\beta) \varphi_\beta(u) du \right\} + \int f^{(0,2)}_{\alpha\beta}(x_\alpha, x_\beta) \varphi_\beta(u) du \right\} + o_p(h^2).
\]

We now turn to the variance part \( T_{2n} \). In Fan, Härdle, Mammen (1997) it is shown that for

\[
w_{i\alpha\beta} = \frac{1}{n} K_h(x_\alpha - X_{i\alpha}, x_\beta - X_{i\beta}) - \frac{\varphi_\alpha(x_\alpha, X_{i\alpha\beta})}{\varphi(x_\alpha, x_\beta, X_{i\alpha\beta})}
\]
(24) \[ T_{2n} = \sum_{i=1}^{n} w_{i\alpha\beta} \sigma(X_i) \varepsilon_i + o_p \left\{ (nh^2)^{-1/2} \right\} \]

with a rate of \( \sqrt{nh^2} \) and it also obeys a Central Limit Theorem.

Finally we want to calculate the variance of the combined estimator \( \tilde{F}_{\alpha\beta}(x_a, x_\beta) - \hat{F}_\alpha(x_a) - \hat{F}_\beta(x_\beta) \). Because of the faster rate of the stochastic term in I than the one in II, it is enough to consider II, i.e. \( \sum_{i=1}^{n} w_{i\alpha\beta} \sigma(X_i) \varepsilon_i + o_p \left\{ (nh^2)^{-1/2} \right\} \). It is easy to show that the variance is then

\[ \| K_\alpha^* \|^2 \int \sigma^2(x) \frac{\varphi^2(x_{\alpha\beta})}{\varphi(x)} dx_{\alpha\beta} \]

QED.

A.2 Proof of Theorem 2

This proof is analogous to that of Theorem 1 for the two dimensional terms. The main difference is that at the beginning the kernel \( K(\cdot) \) has to be replaced by \( K^*(\cdot) \), i.e. \( K^*(u, v) = K(u, v) \pi \mu_{u\beta}^{-1}(K) \) and the weights are

(25) \[ w_{i\alpha\beta} = \frac{1}{nh^2} K^*_{3,h}(x_a - X_{i\alpha}, x_\beta - X_{i\beta}, \frac{\varphi_{\alpha\beta}(X_{i\alpha\beta})}{\varphi(x_{\alpha\beta}, x_{i\alpha\beta})} \]

where \( K^*_3(\cdot, \cdot) = \frac{1}{nh^2} K^*_3(\varphi, \varphi) \).

QED.

A.3 Proof of Theorem 3

Consider the decomposition

\[
\int \tilde{f}_{\alpha\beta}(x_a, x_\beta) \varphi_{\alpha\beta}(x_a, x_\beta) dx_a dx_\beta = 2 \sum_{1 \leq i < j \leq n} H(X_i, \varepsilon_i, X_j, \varepsilon_j) + \sum_{i=1}^{n} H(X_i, \varepsilon_i, X_i, \varepsilon_i) + \\
\int \tilde{f}_{\alpha\beta}(x_a, x_\beta) \varphi_{\alpha\beta}(x_a, x_\beta) dx_a dx_\beta + 2h^2 \int \tilde{f}_{\alpha\beta}(x_a, x_\beta) B_1(x_a, x_\beta) \varphi_{\alpha\beta}(x_a, x_\beta) dx_a dx_\beta + o_p(h^2)
\]

in which

\[
H(X_i, \varepsilon_i, X_j, \varepsilon_j) = \varepsilon_i \varepsilon_j \int \frac{1}{n^2} (w_{i\alpha\beta} - w_{i\alpha})(w_{j\alpha\beta} - w_{j\alpha})(w_{j\beta} - w_{j\beta}) \sigma(X_i) \sigma(X_j) \varphi_{\alpha\beta}(x_a, x_\beta) dx_a dx_\beta
\]

with \( w_{i\alpha} \), \( w_{i\beta} \) and \( w_{i\alpha\beta} \) as in equation (20) and (23).
We first simplify $H(X_i, \varepsilon_i, X_j, \varepsilon_j)$ by substituting alternatively $u = (x_\alpha - X_{i\alpha})/h$, $v = (x_\beta - X_{i\beta})/h$.

$$H(X_i, \varepsilon_i, X_j, \varepsilon_j) = \frac{\varepsilon X_{i\alpha}}{n^2} \int \left\{ K(u)K(v) \frac{\varphi_{\alpha\beta}(X_{i\alpha})}{\varphi(X_i)} - K(u) \frac{\varphi_{\beta}(X_{i\beta})}{\varphi(X_i)} - K(v) \frac{\varphi_{\alpha\beta}(X_{i\alpha})}{\varphi(X_i)} \right\}$$

$$\times \left\{ K(u + \frac{X_{i\alpha} - X_{j\alpha}}{h})K(v + \frac{X_{i\beta} - X_{j\beta}}{h}) \frac{\varphi_{\alpha\beta}(X_{j\alpha})}{\varphi(X_{i\alpha}, X_{i\beta}, X_{j\alpha}, X_{j\beta})} - K(u + \frac{X_{i\alpha} - X_{j\alpha}}{h}) \frac{\varphi_{\alpha\beta}(X_{j\alpha})}{\varphi(X_{i\alpha}, X_{i\beta}, X_{j\alpha}, X_{j\beta})} \right\}$$

$$\times \sigma(X_i) \sigma(X_j) \varphi_{\alpha\beta}(X_{i\alpha}, X_{i\beta}) \varphi_{\alpha\beta}(X_{j\alpha}, X_{j\beta}) \frac{1 + o_p(1)}{d}$$

Denoting by $K^{(r)}$ the $r$-fold convolution of the kernel $K$, one obtains

$$\sum_{1 \leq i < j \leq n} H(X_i, \varepsilon_i, X_j, \varepsilon_j) = \sum_{1 \leq i < j \leq n} (H_1 + H_2 + H_3 + H_4 + H_5) \{1 + o_p(1)\}$$

where

$$H_1 = \frac{\varepsilon X_{i\alpha}}{n^2 h^2} \sum_{r=1}^{n} K^{(2)} \left( \frac{X_{i\alpha} - X_{j\alpha}}{h} \right) K^{(2)} \left( \frac{X_{i\beta} - X_{j\beta}}{h} \right) \varphi_{\alpha\beta}(X_{i\alpha}, X_{i\beta}, X_{j\alpha}, X_{j\beta})$$

$$H_2 = -\frac{\varepsilon X_{i\alpha}}{n^2 h} \sum_{r=1}^{n} K^{(2)} \left( \frac{X_{i\alpha} - X_{j\alpha}}{h} \right) \varphi_{\alpha\beta}(X_{i\alpha}, X_{i\beta}, X_{j\alpha}, X_{j\beta}) \left\{ K^{(2)} \left( \frac{X_{i\alpha} - X_{j\alpha}}{h} \right) \varphi_{\beta}(X_{i\alpha}) + K^{(2)} \left( \frac{X_{i\beta} - X_{j\beta}}{h} \right) \varphi_{\beta}(X_{i\beta}) \right\}$$

$$H_3 = -\frac{\varepsilon X_{i\alpha}}{n^2 h} \sum_{r=1}^{n} K^{(2)} \left( \frac{X_{i\alpha} - X_{j\alpha}}{h} \right) \varphi_{\alpha\beta}(X_{i\alpha}, X_{i\beta}, X_{j\alpha}, X_{j\beta}) \left\{ K^{(2)} \left( \frac{X_{i\alpha} - X_{j\alpha}}{h} \right) \varphi_{\beta}(X_{i\alpha}) + K^{(2)} \left( \frac{X_{i\beta} - X_{j\beta}}{h} \right) \varphi_{\beta}(X_{i\beta}) \right\}$$

$$H_4 = -\frac{\varepsilon X_{i\alpha}}{n^2 h} \sum_{r=1}^{n} K^{(2)} \left( \frac{X_{i\alpha} - X_{j\alpha}}{h} \right) \varphi_{\alpha\beta}(X_{i\alpha}, X_{i\beta}, X_{j\alpha}, X_{j\beta}) \left\{ K^{(2)} \left( \frac{X_{i\alpha} - X_{j\alpha}}{h} \right) \varphi_{\beta}(X_{i\alpha}) + K^{(2)} \left( \frac{X_{i\beta} - X_{j\beta}}{h} \right) \varphi_{\beta}(X_{i\beta}) \right\}$$

$$H_5 = -\frac{\varepsilon X_{i\alpha}}{n^2 h} \sum_{r=1}^{n} K^{(2)} \left( \frac{X_{i\alpha} - X_{j\alpha}}{h} \right) \varphi_{\alpha\beta}(X_{i\alpha}, X_{i\beta}, X_{j\alpha}, X_{j\beta}) \left\{ K^{(2)} \left( \frac{X_{i\alpha} - X_{j\alpha}}{h} \right) \varphi_{\beta}(X_{i\alpha}) + K^{(2)} \left( \frac{X_{i\beta} - X_{j\beta}}{h} \right) \varphi_{\beta}(X_{i\beta}) \right\}$$
All of these are symmetric and nondegenerate \( U \)-Statistics. We will derive the asymptotic variance of \( H_1 \) and one will be able to see in the process that all the other \( H_i \)'s are of higher order and thus negligible. Now we calculate

\[
E \left\{ H_1^2(X_1, \varepsilon_1, X_2, \varepsilon_2) \right\} = \frac{1}{n^4h^4} \int K^{(2)}(z) \left( \frac{z_{1\alpha} - z_{2\alpha}}{h} \right) \left( \frac{z_{1\beta} - z_{2\beta}}{h} \right) \varphi_{1\alpha}^2(z_{1\alpha}) \varphi_{2\beta}^2(z_{2\beta})
\times \left\{ \frac{1}{\varphi(z_1)\varphi(z_{1\alpha}, z_{1\beta}, z_{2\beta})} + \frac{1}{\varphi(z_2)\varphi(z_{2\alpha}, z_{2\beta}, z_{1\beta})} \right\}^2 \sigma^2(z_1)\sigma^2(z_2) \varphi(z_1) \varphi(z_2) dz_1 dz_2.
\]

Introducing the change of variable

\[ z_{2\alpha} = z_{1\alpha} - hu, z_{2\beta} = z_{1\beta} - hv \]

we obtain

\[
E \left\{ H_1^2(X_1, \varepsilon_1, X_2, \varepsilon_2) \right\} = \frac{1}{n^4h^2} \int K^{(2)}(u)K^{(2)}(v)\varphi_{1\alpha}^2(z_{1\alpha})\varphi_{2\beta}^2(z_{2\beta})\sigma^2(z_1)\sigma^2(z_1, z_{1\beta}, z_{2\beta})
\times \left\{ \frac{1}{\varphi(z_1)\varphi(z_{1\alpha}, z_{1\beta}, z_{2\beta})} + \frac{1}{\varphi(z_2)\varphi(z_{2\alpha}, z_{2\beta}, z_{1\beta})} \right\}^2 \varphi(z_1)\varphi(z_{1\alpha}, z_{1\beta}, z_{2\beta}) d\gamma_{1\alpha} d\gamma_{1\beta} d\gamma_{2\beta} \{1 + o(1)\},
\]

or

\[
E \left\{ H_1^2(X_1, \varepsilon_1, X_2, \varepsilon_2) \right\} = \frac{4}{n^4h^2} \left\{ K^{(2)}(u)K^{(2)}(v)\varphi_{1\alpha}^2(z_{1\alpha})\varphi_{2\beta}^2(z_{2\beta})\sigma^2(z_1)\sigma^2(z_1, z_{1\beta}, z_{2\beta})
\times \left\{ \frac{1}{\varphi(z_1)\varphi(z_{1\alpha}, z_{1\beta}, z_{2\beta})} + \frac{1}{\varphi(z_2)\varphi(z_{2\alpha}, z_{2\beta}, z_{1\beta})} \right\}^2 \varphi(z_1)\varphi(z_{1\alpha}, z_{1\beta}, z_{2\beta}) \right\} d\gamma_{1\alpha} d\gamma_{1\beta} d\gamma_{2\beta} \{1 + o(1)\}.
\]

To prove that \( \sum_{i<j} H_1(X_i, \varepsilon_i, X_j, \varepsilon_j) \) is asymptotically normal, one needs to show that

\[
E \left\{ G_1^2(X_1, \varepsilon_1, X_2, \varepsilon_2) \right\} + n^{-1} E \left\{ H_1^4(X_1, \varepsilon_1, X_2, \varepsilon_2) \right\} = o_p \left[ \left\{ E H_1^2(X_1, \varepsilon_1, X_2, \varepsilon_2) \right\}^2 \right]
\]

where

\[
G_1(x, \varepsilon, y, \delta) = E \left\{ H_1(X_1, \varepsilon_1, x, \varepsilon)H_1(X_1, \varepsilon_1, y, \delta) \right\},
\]

see Hall (1984).

**Lemma A3** As \( h \to 0 \) and \( nh^2 \to \infty \)

\[
n^{-1} E \left\{ H_1^4(X_1, \varepsilon_1, X_2, \varepsilon_2) \right\} = O_p(n^{-9}h^{-6}) = o_p \left[ \left\{ E H_1^2(X_1, \varepsilon_1, X_2, \varepsilon_2) \right\}^2 \right].
\]

**Proof.** As in the case of the second moment, the fourth moment can be calculated as

\[
E \left\{ H_1^4(X_1, \varepsilon_1, X_2, \varepsilon_2) \right\} = \frac{h^2}{n^8h^8} \int K^{(2)}(u)K^{(2)}(v)\varphi_{1\alpha}^4(z_{1\alpha})\varphi_{2\beta}^4(z_{2\beta})\sigma^4(z_1)\sigma^4(z_1, z_{1\beta}, z_{2\beta})
\times \left\{ \frac{1}{\varphi(z_1)\varphi(z_{1\alpha}, z_{1\beta}, z_{2\beta})} + \frac{1}{\varphi(z_2)\varphi(z_{2\alpha}, z_{2\beta}, z_{1\beta})} \right\}^4 \varphi(z_1)\varphi(z_{1\alpha}, z_{1\beta}, z_{2\beta}) \{1 + o_p(1)\}
\]

which implies that

\[
n^{-1} E \left\{ H_1^4(X_1, \varepsilon_1, X_2, \varepsilon_2) \right\} = O_p(n^{-9}h^{-6}) = \left( E H_1^2(X_1, \varepsilon_1, X_2, \varepsilon_2) \right)^2 O_p(n^{-1}h^{-2})
\]

which proves the lemma as \( n^{-1} h^{-2} \to 0. \)
Lemma A4. As \( h \to 0 \) and \( nh^2 \to \infty \)

\[
G_1(x, \varepsilon, y, \delta) = \frac{2\varepsilon \delta \varphi(x) \varphi(y) \sigma(x) \sigma(y)}{n^4h^2} K[4] \left( \frac{x_\alpha - y_\alpha}{h} \right) K[4] \left( \frac{x_\beta - y_\beta}{h} \right) \times 
\]

\[
\int \left\{ \frac{1}{\varphi(x)\varphi(y)\varphi(z_\alpha, z_\beta)} + \frac{1}{\varphi(x, x_\beta, z_\beta)\varphi(x, x_\beta, y_\beta)} \right\} \varphi^2(z_\beta) \sigma^2(x, x_\beta, z_\beta) d\sigma \{1 + o(1)\} 
\]

Proof. According to the definition of \( G_1 \)

\[
G_1(x, \varepsilon, y, \delta) = E \left\{ H_1(X_1, \varepsilon_1, x, \varepsilon) H_1(X_1, \varepsilon_1, y, \delta) \right\} = \frac{\varepsilon \delta}{n^4h^4} \times 
\]

\[
E \left[ K[2] \left( \frac{X_1 - x_\alpha}{h} \right) K[2] \left( \frac{X_1 - x_\beta}{h} \right) \left\{ \frac{1}{\varphi(x_1)\varphi(x_1, x_\beta, X_1, x_\beta)} + \frac{1}{\varphi(X_1)\varphi(X_1, X_1, x_\beta, x_\beta)} \right\} \times \varphi(x)\varphi(x_\beta)\varphi(y)\sigma(x)\sigma(y) \right] 
\]

or

\[
G_1(x_\alpha, x_\beta, y_\alpha, y_\beta) = \frac{\varepsilon \delta \varphi(x)\varphi(y)\sigma(x)\sigma(y)}{n^4h^4} \int \varphi^2(z_\beta)\sigma^2(z_\beta) d\sigma \{1 + o(1)\} 
\]

Introducing the change of variable

\[
z_\alpha = x_\alpha + hu, z_\beta = x_\beta + hv 
\]

we obtain

\[
G_1(x_\alpha, x_\beta, y_\alpha, y_\beta) \times K[2] (u) K[2] (v) \left\{ \frac{1}{\varphi(x)\varphi(x, x_\beta, z_\beta)} + \frac{1}{\varphi(x, x_\beta, z_\beta)\varphi(x, x_\beta, x_\beta)} \right\} \left( u + \frac{x_\alpha - y_\alpha}{h} \right) 
\]

\[
\times K[2] (v + \frac{x_\beta - y_\beta}{h}) \left\{ \frac{1}{\varphi(y)\varphi(y, y_\beta, z_\beta)} + \frac{1}{\varphi(x, x_\beta, z_\beta)\varphi(x, x_\beta, y_\beta)} \right\} \times \varphi(x_\alpha, x_\beta, z_\beta) h^2 dudv \{1 + o(1)\}. 
\]
Using convolution notation, one has

\[
G_1(x, \varepsilon, y, \delta) = \frac{\varepsilon}{n^4h^2} \frac{\varphi(x_{\alpha \beta}) \varphi(x_{\beta \gamma}) \sigma(x) \sigma(y)}{\varphi(x_{\alpha \beta}, x_{\beta \gamma})} K^{(4)} \left( \frac{x_{\alpha} - y_{\alpha}}{h} \right) K^{(4)} \left( \frac{x_{\beta} - y_{\beta}}{h} \right) \times
\]

\[
\int \left\{ \frac{1}{\varphi(x) \varphi(x_{\alpha \beta}, z_{\alpha \beta})} + \frac{1}{\varphi(x_{\alpha \beta}, x_{\beta \gamma})} \frac{1}{\varphi(y) \varphi(y_{\beta \gamma}, z_{\beta \gamma})} + \frac{1}{\varphi(x_{\alpha \beta}, y_{\beta \gamma})} \right\} \frac{1}{\varphi(x_{\alpha \beta})} \sigma^2(x_{\alpha}, x_{\beta}, z_{\alpha \beta}) d^2 z_{\alpha \beta} \{1 + o(1)\}
\]

or

\[
G_1(x, \varepsilon, y, \delta) = \frac{2\varepsilon}{n^4h^2} \frac{\varphi(x_{\alpha \beta}) \varphi(x_{\beta \gamma}) \sigma(x) \sigma(y)}{\varphi(x_{\alpha \beta}, x_{\beta \gamma})} K^{(4)} \left( \frac{x_{\alpha} - y_{\alpha}}{h} \right) K^{(4)} \left( \frac{x_{\beta} - y_{\beta}}{h} \right) \times
\]

\[
\int \left\{ \frac{1}{\varphi(x) \varphi(y_{\beta \gamma}, z_{\beta \gamma})} + \frac{1}{\varphi(x_{\alpha \beta}, z_{\alpha \beta})} \frac{1}{\varphi(x_{\beta \gamma}, y_{\beta \gamma})} \right\} \frac{1}{\varphi(x_{\alpha \beta})} \sigma^2(x_{\alpha}, x_{\beta}, z_{\alpha \beta}) d^2 z_{\alpha \beta} \{1 + o(1)\}
\]

which is what we set out to prove. By techniques used in the two previous lemmas, one has

**Lemma A5** As \( h \to 0 \) and \( nh^2 \to \infty \)

\[
E \{ G_1(X_1, \varepsilon_1, X_2, \varepsilon_2) \}^2 = O(n^{-8}h^{-2}) = o \left[ \{ E H_1(X_1, \varepsilon_1, X_2, \varepsilon_2) \}^2 \right].
\]

Lemmas A3 and A5, plus the Martingale Central Limit Theorem of Hall (1984) implies

**Proposition A1** As \( h \to 0 \) and \( nh^2 \to \infty \)

\[
\sum_{1 \leq i < j \leq n} H(X_i, \varepsilon_i, X_j, \varepsilon_j) \overset{L^2}{\to} N\left( \begin{array}{c} 0, \frac{2}{\int K^{(4)}(z_{\alpha \beta}) \varphi(z_{\alpha \beta})} \sigma^2(z_{1 \alpha}) \sigma^2(z_{1 \beta}) d^2 z_{1 \alpha \beta} \end{array} \right).
\]

The “diagonal” term \( \sum_{i=1}^{n} H(X_i, \varepsilon_i, X_i, \varepsilon_i) \) has the following property

**Proposition A2** As \( h \to 0 \) and \( nh^2 \to \infty \)

\[
\sum_{i=1}^{n} H(X_i, \varepsilon_i, X_i, \varepsilon_i) = \frac{2\{ K^{(4)}(0) \}^2}{nh^2} \int \frac{\phi_{\alpha \beta}(z_{\alpha \beta})}{\varphi(z)} \sigma^2(z) dz + O_p \left( \frac{1}{\sqrt{n}nh^2} \right)
\]

**Proof**. This follows by simply calculating the mean and variance of \( H(X_1, \varepsilon_1, X_1, \varepsilon_1) \).

Putting these results together, Theorem 3 is proved.

QED.
