Preface

Privatisation of hospitals, i.e. a change in their type of ownership from the municipal and private-non-profit¹ type to the private profit-oriented² type, has been the subject of heated debate ever since this development began back in the early 1990s. To objectivise this debate, the Fact Book „Significance of Privately Owned Hospitals“) was prepared in 2009 using data from 2006. The aim was to provide a scientific assessment of hospital privatisation in Germany by presenting and evaluating relevant key ratios relating to the hospital market, differentiated by type of ownership.

The present, updated Fact Book aims i) to put the analyses already conducted using data from 2006 on the current 2009 data basis, ii) to throw light on additional issues, and iii) to limit the sampling to only those hospitals with a care mandate. Thus, university hospitals are not included because in addition to care delivery they also conduct research and teaching, with the result that their key ratios are not directly comparable with those of non-university hospitals. Likewise, purely psychiatric or psychotherapeutic as well as purely day-care and night-care clinics are kept out of the analysis. The Study thus confines itself to the empirically observable influencing factors of hospital privatisation. Naturally, this can only include some of all conceivable influencing factors.

We would like to thank Corinna Hentschker and Adam Pilny for their valuable assistance in preparing the Study. We also thank the German Federal Statistical Office (*Statistisches Bundesamt*) for providing official data and Anette Hermannowski, Julica Bracht, Ailine Lingnau, Claudia Lohkamp, Lutz Morgenroth, Daniela Schwindt and Benedict Zinke for their organisational help. The authors alone are responsible for the Study's content and any errors.

Privately Owned Hospitals

1. Introduction

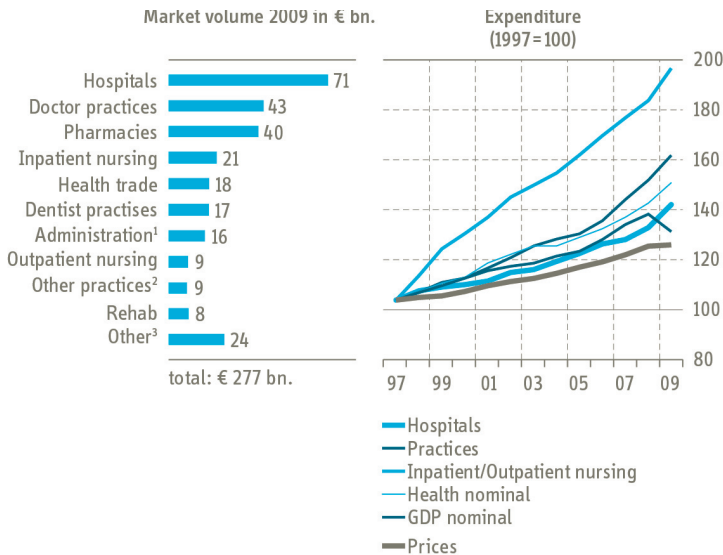

1. Introduction

The tremendous importance of the healthcare and hospital market has been cited time and again, not only in terms of providing high-quality and generalised care to the population but also in terms of its economic dimension as a major employer (Beivers and Minartz (2011b)). As Diagram 1 shows, the German healthcare market reached a volume of roughly € 277 billion in 2009. This implies growth of € 14 billion or 5.2% compared with 2008. What is remarkable is that this is the largest growth seen in the past 15 years. At the same time, gross domestic product plunged in the wake of the financial crisis, with the result that healthcare expenditure in 2009 for the first time accounted for 11.5% of GDP – up from 10.5% in the previous year (Augurzky et al. 2011). The hospital sector alone accounts for the biggest chunk of all sectors within the healthcare system, with a volume of some € 71 billion. That translates into a share of 25.6% in the aggregate healthcare market.

Privately Owned Hospitals

Diagram 2

Number of inpatient cases and outpatient operations

2005 to 2009; in m

Source: RWI; Statistisches Bundesamt (Grunddaten).

When it is moreover considered that roughly 1.1 million persons are employed in German hospitals (Statistisches Bundesamt: Grunddaten), the huge importance for employment policy becomes obvious as well.

Market volume is reflected most impressively in the hospitals' service volumes. The number of inpatient cases increased by 7.7% between 2005 and 2009 from 16.5 million to 17.8 million (Diagram 2). In addition to full inpatient service volumes, the number of outpatient operations pursuant to section 115b of the German Social Insurance Code V (Sozialgesetzbuch V, SGB V) witnessed a particularly sharp rise: by 32% since 2005, and even by 215% since 2002 (Augurzky et al. 2011).

As already presented in the first Fact Book, the hospital market is undergoing a process of sweeping changes to which there is currently no end in sight. For example, the number of hospitals declined by roughly 14% from 1991 to 2010. A similar trend can be observed with the number of beds (-25%) and duration of stay (-44%) (Statistisches Bundesamt 2011: Grunddaten). In a mirror image to this is the smart rise in the number of full inpatient cases (+24%) – which reflects an increase in efficiency. These changes have been reinforced by the introduction of case-flat-rate remuneration in hospitals based on diagnosis-related groups

2. Special features of privately owned hospitals

(DRGs). From the outset of this transformation process, an increasing switch in ownership of hospitals in favour of private, profit-oriented companies has also been observed.

This dynamic trend, often referred to as “privatisation of the hospital market”, is assessed in different ways by the individual players of the healthcare system. Time and again fears of a possible trade-off between private hospital owners’ intention of generating profits on the one hand and ensuring high-quality and generalised hospital care on the other are voiced. The key purpose of the present Fact Book is to examine these with the aid of detailed empirical analyses.

2. Special features of privately owned hospitals

Essentially, privately owned hospitals are distinguished from municipal and non-profit facilities by the fact that private equity capital is employed in the company.³ This results in advantages and disadvantages compared with other hospitals. On the one hand, private funds are not provided for free. This is a well-known feature of debt capital, for which interest is charged. The use of private equity capital also comes at a cost in the form of dividends paid out each year. This deprives the hospital of a certain capacity to invest, but on the other hand has the advantage of allowing the hospital to tap the capital markets for funds. That in turn increases investment capacity considerably because it is only by paying out part of their profit that hospitals become attractive for external providers of capital. It is thus a give-and-take process. For the German economy as a whole, it is an advantage for private capital to be invested in the healthcare system. Non-profit-oriented hospitals do not have this option. They can only resort to scarce government grants and debt capital.⁴ Without sufficient investment, though, it is often difficult for a hospital to optimise its clinical processes.

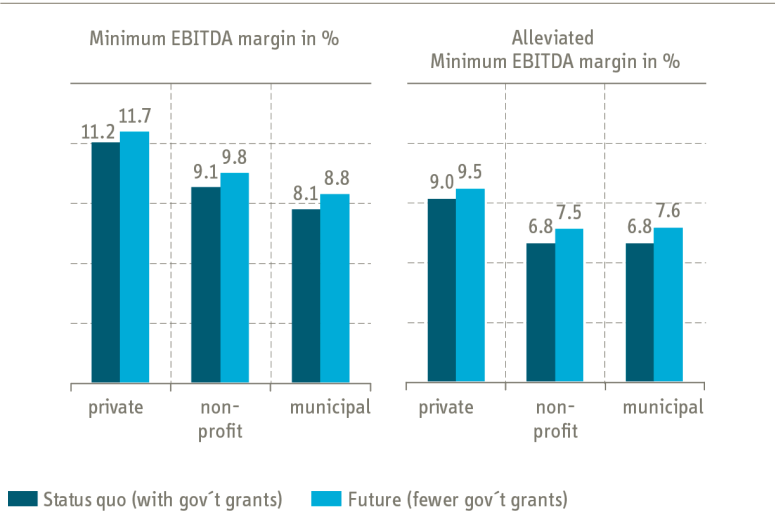

The facility’s profit-generating intention is thus justified by the capital cost of privately invested equity capital. But at the same time, profits are not guaranteed. Losses are also possible. Providers of capital take an entrepreneurial risk. The

³ By contrast, private debt capital is used by hospitals of any ownership type.

⁴ Note, here, that debt capital, frequently in the form of loans from banks, also comes at an interest charge. This also deprives the hospital of funds. Funds are also removed from the hospital as a result of remuneration of the hospital’s staff. However, this is a normal part of a production process. Factors of production, notably labour and capital, are employed to produce the desired product. It is a matter of course that in such production process costs are incurred by the factors of production.

Privately Owned Hospitals

customary rate of return on capital thus also includes a risk premium; the greater the likelihood of a loss being generated on the capital employed, the higher the risk premium is.

In a sample calculation we assume that interest of 8% per annum, including the risk premium, is payable as the rate of return on the privately invested equity capital, whereas that rate of return for equity capital of non-profit hospitals is only 3% and that of municipal hospitals 0%, with the rate being 4% for debt capital and 0% for government grants. Under these assumptions, a minimum necessary overall return on capital by ownership type can be derived. In this context we assume an average capital structure for each ownership type. Assuming, moreover, typical rates of depreciation on fixed assets as well as an average asset structure are assumed, it thus becomes possible to calculate the depreciation rates as well as a

minimum necessary operating result overall (EBITDA margin⁵) for each ownership type (Diagram 3). Diagram 4 shows how it is determined in the example of a privately owned hospital. This is performed analogously for the other ownership types.

A further important advantage of hospitals with private owners is that they frequently have a professional supervisory body and a profit-oriented management. The supervisory body per se is more homogenous and its members pursue similar interests, above all efficient provision of the hospital's services and ongoing improvement in its own competitive position. Going hand in hand with this is an interest in high-quality services so as to successfully vie for patients in competition with other hospitals. In particular, the supervisory body as a rule does not pursue any other objectives that might be to the detriment of efficiency and quality.

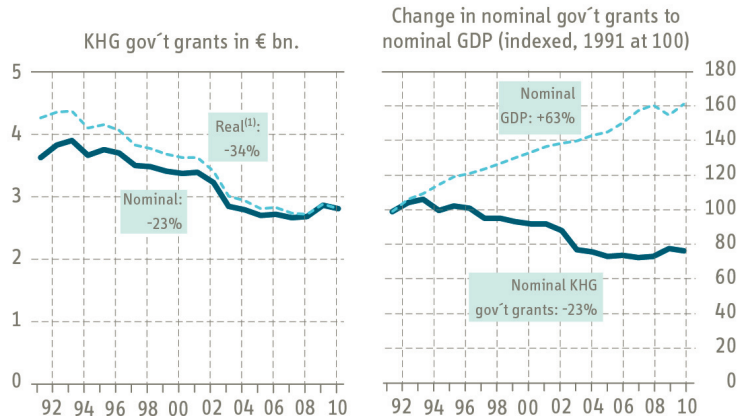

⁵ EBITDA = operating earnings, i.e. income after deducting personnel and material costs. It stands for "Earnings before interest, taxes, depreciation, and amortization". It is a business ratio that provides a relatively good approximation of a company's cash flow. EBITDA margin is the ratio of EBITDA to income.

Privately Owned Hospitals

Diagram 5

Gov't grants under the KHG

1991 bis 2010; in Mill. €

Source: RWI; DKG (2011). – ¹Deflated by consumer goods price index.

In this connection it has to be assumed that supervisory bodies of privately owned entities place much greater emphasis on a success-oriented executive body that manages the fate of the company under its own responsibility and is measured by its achievement of the company's targets. Here, such supervisory body does not interfere in the day-to-day business of the company but rather is concerned with the long-term corporate strategy. Its greater independence from decisions by local levels of government makes it easier for the management of private but also many non-profit hospitals to not only identify rationalisation potential but also to actually exploit such potential.

Just how important private capital is for the German hospital system is seen in the dearth of government grants having led to a noticeable investment gap over the past years. Germany has what is referred to as a dual hospital finance system. Under the Hospitals Financing Act (*Krankenhausfinanzierungsgesetz, KHG*) (section 9 (1) KHG), the federal states bear the costs of investment out of tax funds (Beivers and Minartz 2011a; Neubauer 2007). Under the KHG, the hospitals at least have a claim against the federal states for funding of their investment costs. The precondition for this is that the facility has been admitted to the state hospital requirement plan. Current operating costs, however, are accounted for with the patients or health insurance funds via DRGs, supplementary remuneration and daily nursing rates. Consequently, remuneration does not include any investment

3. Data basis

cost components. This results in two management systems based on two different regulatory policies being used side by side, which is something that naturally leads to conflicts (these can also actually be observed in Germany). This results among other things from the fact that the design of the remuneration system is subject to the prerogative of the German Parliament and hospital planning to that of the federal states (cf. Neubauer 2007). The area of investment financing is thus running into difficulties with the noticeable reduction in government grants seen for several years now (Diagram 5).

Taking the annual investment requirement of 10% of a hospital's revenue regarded as necessary, a cumulative investment gap totalling € 30 billion has arisen since 1991, according to estimates of the RWI (Augurzky et al. 2011). That said, hospitals are increasingly filling this gap by investing out of own funds, with the result that the actual investment backlog can be put only at roughly € 14 billion. The falling rate of government grants can be seen in hospitals' balance sheets. Average investment capacity of the hospitals is indeed poor. The EBITDA margin including government grants averaged 8% in 2009 – to ensure sufficient investment, the level, depending on the ownership type, should be well above that. In this sense, only roughly 36% of all hospitals have full investment capacity (Augurzky 2012).

3. Data basis

The basis for the data of this Fact Book is taken from the official hospital data of the Federal Statistical Office (*Statistisches Bundesamt*) (Diagram 6). The data used were the (i) basic data on inpatient service volumes from 1996 to 2009 (*Statistisches Bundesamt: Grunddaten*). On the cost side, the (ii) cost statement of the hospitals provides comparable data on personnel and material costs for the years 2002 to 2009 (*Statistisches Bundesamt: Kostennachweis*).

These data are publicly available in aggregated form. In section 5, we resort to such data to show longer time series. However, we always confine ourselves to general hospitals⁶, i.e. exclude purely psychiatric or psychotherapeutic or purely day- and night-care facilities because it is not even remotely possible to measure their outcome in case-mix points. Moreover, we exclude university hospitals because in addition to care delivery they also conduct research and teaching and it is likewise not even remotely possible to measure their overall outcome in case-

⁶ General hospitals are those having beds available in full inpatient departments, with such beds not being kept available exclusively for psychiatric, psychotherapeutic and neurology patients. Purely day and night facilities are excluded (*Statistisches Bundesamt 2011: Grunddaten*).

Privately Owned Hospitals

Source: RWI.

mix points.⁷ For 2009, data of 1,780 general hospitals are available (including 34 university hospitals), of which 563 under private ownership and 661 under non-profit and 522 under public ownership (Table 1).

⁷ However, university hospitals can be removed only approximately from the aggregated data because since 2006 it has no longer been the case that all university hospitals are under public ownership (and thus it is impossible simply deduct their figures from those of all public hospitals). Insofar, a part of that has to be deducted from the figures of the private hospitals after 2006 with the aid of a key.

3. Data basis

Table 1

Selection settings „care hospitals and general hospitals“

Selection of „general hospitals“	563	661	522	34	1 780

Source: RWI; FDZ (2011); Statistisches Bundesamt (Grunddaten).

That said, the publicly accessible aggregated data have the disadvantage of not allowing for any further refinements in the analyses. For example, hospitals without a care mandate, which are not the subject matter of the Fact Book, are not eliminated. These include many small private hospitals, for example. However, the data basis can be adjusted for all non-relevant hospitals by using the original data available from the research data centres of the State Statistical Offices. Only approved hospitals⁸ or those with a care mandate⁹ which provide DRG services (hereinafter referred to in short as “care hospitals”¹⁰) are included. The drawback in this regard is that the analyses are much more involved and key ratios are provided only for 2005 and for the currently available year 2009. Section 4 refers to these data. However, they do not allow for any time series analyses.

⁸ Approved hospitals are hospitals that are admitted to a federal state's hospital requirement plan (cf. section 6 (1) KHG); in 2009 there were 1,481 general approved hospitals (Statistisches Bundesamt 2011).

⁹ Hospitals with a care mandate pursuant to section 108 no. 3 SGB V are authorised to provide hospital treatment to statutory health insured members based on a care mandate with the state associations of health insurance funds and the associations of other substitute funds; in 2009 there were 87 general hospitals with a care mandate (Statistisches Bundesamt 2011).

¹⁰ With the care hospitals, by analogy to the general hospitals, the purely psychiatric and psychosomatic hospitals were removed from the calculation. Since the detailed data basis of the FDZ makes it possible to measure psychiatric-neurological hospitals separately, these, however, were not removed from the calculation because their services are to a certain extent remunerated with DRGs. That explains why the number of other non-profit and municipal care hospitals in Table 1 is larger than the number of general hospitals.

Privately Owned Hospitals

Diagram 7

Comparison of sample and selection of care hospitals

2009; share as % of all hospitals

Source: RWI; FDZ (2011).

In keeping with this selection, data from a total of 1,663 care hospitals, of which 412 under private, 702 under non-profit and 549 under public ownership, are available to us for 2009, and data from 1,762 hospitals for 2005. Table 1 also shows how the general pool changes as a result of the selection of care hospitals for 2005 and 2009.

For some analyses (especially those based on economic key ratios) the (iii) RWI annual financial statement data are used. This sampling includes 687 annual financial statements from 2008 and 366 from 2009. They cover 1,035 hospitals and allow for analyses of the hospitals' financial situation by ownership type. The ownership structure is reflected very well by the available annual financial statements (Diagram 7). To weight the number of cases, the (iv) CMLs per hospital provided by the WIdO were also used. In this way, it is possible using the case mix to reflect a hospital's outcome much better than merely using the number of cases. Furthermore, the (v) survey of the Federal Association of Private Hospitals in Germany (BDPK) makes it possible to show the SHI share of patients treated in private hospitals. For the analysis of patient satisfaction, (vi) patient surveys of the health insurance fund Techniker Krankenkasse from 2006, 2008 and 2010 were used.

For examining the owner-specific quality of the services provided, the (vii) quality data of the Federal Agency of Quality Assurance (BQS) from data year 2008 were used. These data relate to over 3.5 million patient cases from more than 1,700 hospitals (BQS 2009). For our analyses, we were able to resort to the BQS assessments of 32 individual indicators. These can be used in different ways: each individually, grouped into three categories (process, indication and results quality)

4. Detailed analyses of care hospitals

or grouped into one category. For our analyses, the individual indicators for each hospital were grouped into a quality measure with three categories: (1) “qualitatively conspicuous”, i.e. the percentage of indicators with qualitative conspicuities is greater than 5%; (2) “under observation”, i.e. the sum of the percentage of indicators with conspicuities and of the percentage of indicators under observation is greater than 5% and the hospital is not qualitatively conspicuous; or (3) “qualitatively inconspicuous” for all other hospitals.¹¹

4. Detailed analyses of care hospitals

4.1 Market shares

Diagram 8 shows the changes in the market shares of the care hospitals between 2005 and 2009. During this period, the share of private hospitals increased by 4.8 percentage points with reference to the number of hospitals, by 3.7 percentage points with reference to the number of beds and by 3.9 percentage points with reference to the number of cases. It becomes apparent that the private hospitals on average acquired more small hospitals. It also emerges that private hospitals keep available a disproportionately high share of intensive care beds. Furthermore, a persistent market consolidation on the hospital market, i.e. mergers in the hospital sector, can be observed (Augurzky et al. 2011) – driven in particular by the hospital chains under private, but increasingly also those under public and non-profit ownership.

4.2 Efficiency

To cover their capital costs, private hospital owners have to generate a return on their capital employed. This calls for a high level of efficiency. That means adhering to stringent cost and revenue management as well as high (labour) productivity. To minimise costs, it is necessary to reap economies of scale through high occupancy, achieve specialisation of services volumes as well as optimise clinical processes in addition to cost-sensitive management. The merger into a group can moreover unlock networking reserves referred to as “economies of scope”. Here, the private hospitals lead the way, as shown among other things by the adjusted costs per case-mix point¹² (Diagram 9).

11 BQS (2010); additional information: <http://www.bqs-qualitaetsindikatoren.de>.

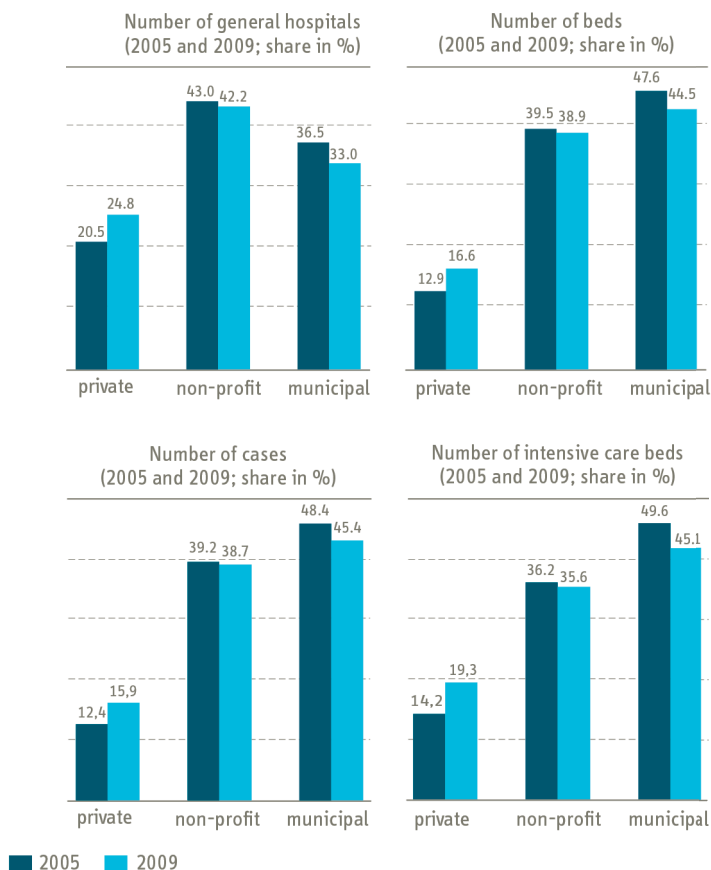

12 Under the DRG system, case mix represents a hospital's case number weighted by severity of treatment. It thus measures a hospital's service volume.

Privately Owned Hospitals

Diagram 8

Market shares of general hospitals

2005 and 2009; in %

Source: RWI; FDZ (2011).

Private hospitals have proportionately higher material costs compared with the other ownership types (Diagram 10). However, the percentage has increased with all ownership types on a comparison between 2005 and 2009. The differences versus the previous Fact Book result because here the costs are shown as a percentage of gross costs and not, as previously the case, as a percentage of revenue. This allows for better comparability. The higher material cost share of the

Source: RWI; FDZ (2011).

private hospitals is presumably explained by a higher ratio of services performed by external entities (i.e. their higher level of outsourcing). This is part of the production process based on economic division-of-labour principles. A glance at the more detailed cost structure (e.g. percentage of medical supplies in material costs) under 4.4 in particular reveals that the private hospitals do not spend less money on medical infrastructure than the other owners.

Privately Owned Hospitals

Diagram 12

Case-mix points per full-time employee

2009

Source: RWI; FDZ (2011); WIdO (2011).

Personnel costs, at roughly 57% of gross costs, are proportionately lower with the private providers (Diagram 11). This might result, firstly, from the fact that hospitals under private ownership prefer in-house wage agreements and are not bound by rigid industry-wide collective bargaining rules. This allows for a higher degree of performance-linked remuneration and greater freedom in the terms agreed for

4. Detailed analyses of care hospitals

Diagram 13

Number of cases per full-time employee

2005 and 2009

Source: RWI; FDZ (2011).

individual employment contracts as well as additional possibilities of retaining qualified staff. Secondly, it reflects the possibly greater level of outsourcing of private hospitals already mentioned.

The higher (labour) productivity of the private hospitals is also reflected by the key ratio “case-mix points per full-time employee” (Diagram 12). At 30.4, the private hospitals are well ahead of the others. This can be explained by the lower costs per case-mix point. It is conceivable that this is accompanied by a higher workload of the staff. Empirically, the available data do not allow productivity on the one hand and workload on the other to be separated. However, a disproportionately high workload with an average remuneration cannot be sustained in the long run given the current competition for qualified staff. If, moreover, case numbers per full-time employee are compared, i.e. approximately the number of patients cared for per full-time employee, the employee/patient ratio with private hospitals is even smaller (Diagram 13).

Higher productivity does not necessarily mean a higher workload if workflow processes are designed intelligently, thus reducing inefficiencies. In addition, performance-linked remuneration can result in higher productivity and have a tendency to retain more productive staff. It also has to be assumed that, for example, the areas of cleaning, catering, radiology, laboratory, pick-up and delivery services,

Privately Owned Hospitals

sterilisation, referred to as secondary services with the private hospitals, are more frequently performed by external service providers (outsourcing), reducing the number of full-time staff.

4.3 Earnings strength and investment capacity

The efficiency of the private hospital owners is reflected in their earnings strength. For example, their average EBITDA margin (incl. government grants) was roughly 10.6% of income¹³ in 2009 and thus significantly higher than with non-private hospitals (Diagram 14). Looking at the EBITDA margin excluding government grants, i.e. operating income from own strength, the gap between private and other ownership types is even greater because private hospitals resort to a lesser extent to government grants.

From EBITDA, capital employed is financed. On the one hand, it can be used to finance re-investments for preserving assets. On the other, it provides return on capital to finance debt and equity capital for investments. It is thus a relatively good measure of a company's investment capacity. On the basis of the minimum EBITDA margin defined by way of example in section 2, it allows for an estimate of the average investment capacity of hospitals by ownership type (Diagram 15). Only

Diagram 14

EBITDA margins

2009; as % of total income

Source: RWI; FDZ (2011).

¹³ According to the available HGB balance sheets, income in this regard corresponds to sales plus other operating income.

4. Detailed analyses of care hospitals

Diagram 15

Investment capacity of hospitals

Source: HCB, RWI; FDZ (2011).

17% of the private hospitals had no capacity to invest in 2009, compared with 46% in the case of the municipal facilities. Indeed, the private hospitals used a large share of their income for investments (9.7%), versus 5.4% with their non-profit and 6.7% with their municipal counterparts (Diagram 16).¹⁴

Whereas the private hospitals use significantly fewer public resources in the form of government grants and thus in relative terms place a smaller burden on taxpayers, they conversely, by paying taxes on their profits, even make to contribution to financing the State's obligations towards society. This is illustrated by a comparison of the special item ratio (Diagram 17). Special items are the cumulative government grants received (after depreciation). The private hospitals resort less to public funding. At the same time, they generate a higher net profit on which

¹⁴ The investments were derived from the change in fixed assets over two years. Investments for acquiring a hospital were approximately eliminated so that investments actually refer to the improvement in corporate assets. In the case of the three large private hospital chains Rhön-Klinikum, Helios Kliniken, Asklepios and Sana, investments (excluding acquisition of hospitals) were taken from the annual reports.

Privately Owned Hospitals

they paid roughly 100 million euros in corporate income tax in 2009, significantly more than the other ownership types (Diagram 18). This becomes even clearer when viewed in terms of tax per bed (Diagram 19).

4.4 Participation in healthcare delivery

Among those critical of hospital privatisation, the presumption is that a trade-off is made between profit orientation on the one hand and participation in healthcare delivery on the other. In the previous Fact Book it was shown that profit

orientation is not to the detriment of the medical care delivered to patients, and that private providers are not “cherry pickers”, leaving loss-making business to their public competitors. These statements are confirmed by current analyses of medical service volumes.

The average age of patients treated in private hospitals is higher than in other hospitals (Diagram 20), which may be related to their higher case-mix index (CMI) (Diagram 21). The presumably higher number of secondary diagnoses with older

Privately Owned Hospitals

Source: RWI; FDZ (2011); WIdO (2011).

patients¹⁵ consequently results in a higher CMI under the DRG system. Another reason for the higher CMI may be a greater specialisation among the private hospitals.

As far as costs per case-mix point for medical supplies and drugs are concerned, the private hospitals do not differ significantly from the other hospitals (Diagram 22 and 23). The figures do not provide any indication that private hospitals save on medical supplies at the expense of their patients. Lower costs for drugs with the private hospitals can be explained amongst other things by better purchasing terms as a result of networking effects.

In terms of availability of medical technology infrastructure as measured by the number of large medical equipment units (Diagram 24), there are almost no differences by ownership type.¹⁶ In the area of intensive care beds, the private hospitals even make a disproportionate contribution to the treatment of patients suffering from severe conditions and thus to ensuring (emergency) care (Diagram 25). Lastly, it has to be noted that private hospitals do not treat any more or any fewer

¹⁵ Current studies of the Federal Statistical Office reveal a clear correlation between age of patients and the number of secondary diagnoses at hospital. Whereas 45-64-year-olds on average reveal 3.6 secondary diagnoses, the figure for over-85s, at 7.1 secondary diagnoses, is almost double (Statistisches Bundesamt 2009: Verzeichnis).

¹⁶ Since available capacity is examined here, reference is made to bed capacities kept available instead of case mix.

privately insured patients than the other hospitals do (Box 1). The distribution of statutorily and privately insured patients in the member hospitals of the BDPK is nearly identical to the national distribution for all hospitals.

4. Detailed analyses of care hospitals

Diagram 25

Number of intensive care beds per 100 beds

2005 and 2009

Source: RWI; FDZ (2011).

Box 1:

Privately owned hospitals treat just as many SHI patients

Occasionally private hospitals, given their profit orientation, are said to be mainly interested in treating privately insured patients because they stand to generate higher remuneration from this group of patients. In 2009, roughly 89% of the German population were under statutory (roughly 70 million people) and roughly 11% under private (8.9 million people) health insurance (Federal Association of Statutory Health Insurance Funds – GKV-Spitzenverband 2011). With reference to the number of patients, though, only around 7% to 8% were privately insured due to their lower prevalence rate. A survey conducted by the BDPK among its members in which facilities with a total of 30,000 beds participated revealed that in 2009 roughly 93% of their patients treated were covered by statutory insurance (as in 2005) and that the private facilities in this regard are within the national average.

4.5 Quality

Another important subject is the owner-specific quality of the services provided, which is examined on the basis of the quality data of the Federal Agency of Quality Assurance (BQS) from 2008. Generally, analyses in the Hospital Rating Reports (e.g. Augurzyk et al. 2011) show that the aims of quality and efficiency are not at odds with each other but instead go hand in hand. In the owner-specific assessment of qualitative conspicuities of hospitals (Diagram 26) and the share of the hospitals to be examined (Diagram 27) in the Fact Book therefore do not reveal any

Privately Owned Hospitals

Diagram 26

Hospitals with qualitative conspicuities

2008; share as % of all hospitals

Source: RWI; BQS (2009). – Qualitatively conspicuous if the share of indicators in the hospital with a value of 3, 4 or 5 (according to BQS definition) exceeds 5%.

Diagram 27

Hospitals to be examined

disadvantages of privately owned hospitals either. In fact, it is even the case that the private hospitals less frequently show qualitative conspicuities and are less often among the hospitals to be audited.

In addition to medical quality, the service quality experienced by patients as measured in patient satisfaction is also of great importance. The basis for measuring it is the patient surveys of the health insurance fund Techniker Krankenkasse from 2006 to 2010. Diagram 28 shows that there are no ownership-specific differences in this regard. For all owners, average patient satisfaction is roughly in the range of 77% to 80%.

4. Detailed analyses of care hospitals

Diagram 28

Share of satisfied patients

4.6 Securing regional care delivery

Sufficient generalised healthcare delivery to the population is an important component of the basic services provided by the State enshrined in legislation through the welfare state principle (Art. 20 I of the German Constitution). It also includes generalised healthcare delivery in rural regions. There are critical voices taking the view that it cannot always be provided efficiently and is therefore of less interest for private owners. Insofar, the non-private hospitals would have to take responsibility for it and consequently fare worse on average in terms of efficiency.

Diagram 29 shows the share of rural hospitals by ownership type for 1995 and 2009. First of all it has to be noted that the share of rural hospitals in the case of private owners is similar to that of the non-private hospitals taken together. The share is higher with public hospitals and lower with the non-profit hospitals. Although the share with private and non-profit hospitals is in decline, and on the rise with public hospitals, the changes are not significant. In particular, there is also a large share of rural hospitals among the private facilities newly added since 1995. Note, further, that two thirds of the hospitals on German islands are under private

Privately Owned Hospitals

Diagram 29

Number of hospitals by rurality

1995 and 2009; share in %

Source: RWI; Statistisches Bundesamt (Verzeichnis), BBR (2010). – Rurality is defined by population density of more than 150 inhabitants/km² and without a regional centre of more than 100,000 inhabitants or with a regional centre of over 100,000 inhabitants and a density of under 100 inhabitants/km².

ownership (Table 2).¹⁷ They thus make an important contribution to medical care there both for the local population and for tourists, and help make the regions more attractive overall.

In the following, we further subdivide the rural and municipal¹⁸ hospitals into basic, special and large care providers. In this context, a basic healthcare provider is defined as a hospital which is intended to secure primarily generalised healthcare to the population, is an approved hospital and has between 50 and 300 beds (Beivers and Spangenberg 2008). Specifically, it has to keep available at least surgery and internal medicine capacities. Moreover, there are some large rural hospitals with more than 300 beds (“rural, large”) which likewise secure rural care. By contrast, special hospitals (“special”) are hospitals with up to 300 beds which do not fall under the classification “basic”.

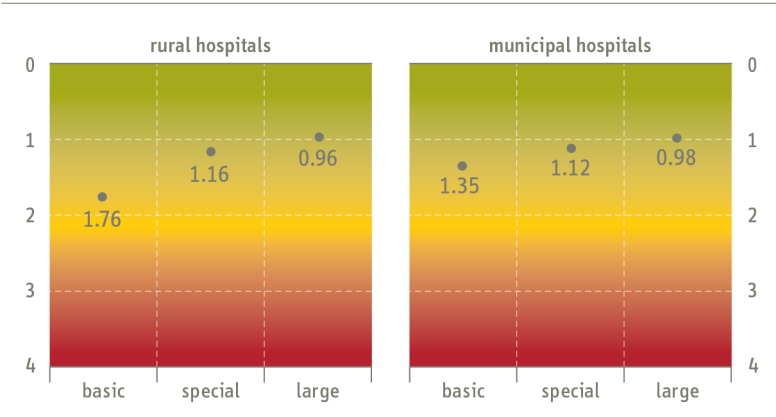

Table 3 shows the distribution of the number of beds both by rurality and by care type. What can be observed is that the private hospitals have a higher share of beds in special hospitals, but nevertheless participate in rural basic care to a similar extent compared with the non-private hospitals: 3.5% of private beds are found with rural basic care providers and 3.8% with the non-private facilities.

¹⁷ The analysis of hospitals on German islands included all islands on which – according to data currently available to RWI – hospitals are located.

¹⁸ Depending on population density and centrality of individual locations, the regions in Germany are assigned by the Federal Office for Building and Regional Planning (BBR) to specific residential structural types of regions and districts. These were used here for the division into the variables of “rural” and “municipal”. For a detailed view, see Augurzyk et al. (2011), pages 123 et seq.

Privately Owned Hospitals

Diagram 30
 Probability of default by care type

Diagram 31
 Probability of default by care type and rurality
 2009; in %

Source: Admed, HCB, RWI. – Selection criterion: Basic: 50 to 300 beds; Large: over 300 beds; large special providers are practically non-existent in this selection. In each case, only the difference between public basic providers (rural and municipal) and all other categories is statistically significant.

5. Time series of general hospitals

11.1% of private beds are attributable to large rural providers and 8.2% in the case of the non-private facilities. But even a direct comparison of private and municipal basic and large providers does not reveal any striking differences. The municipal hospitals have a slightly higher share of beds in rural basic care providers. With regard to large rural providers, there is practically no difference compared with the municipal providers.

A look at the economic situation of the rural basic care providers shows that on average they fare much worse than the other hospitals (Diagram 30). Basic care providers in rural areas have a 0.4 percentage point higher one-year probability of default compared with municipal basic care providers. Rural special hospitals, by contrast, have the same probability of default as municipal special hospitals. The same rings true of large rural and municipal providers.

If a further differentiation is made in this analysis by type of ownership, the picture that emerges is astonishing. To ensure that the sampling of annual financial statements does not become too small as a result of further subdivisions, we group together here the non-profit and private hospitals ("non-municipal") for statistical reasons because their probability of default hardly differs. It now emerges that non-municipal rural basic providers with reference to their probability of default fare just as well as the rural specialists and rural large providers. Obviously, rural basic care does not automatically have to be inefficient (Diagram 31).

5. Time series of general hospitals

In this section, key ratios are shown as far as possible over time. The basis for this is provided by the publicly accessible data of the Federal Statistical Office and the annual financial statements of hospitals. A selection by "care hospitals" is therefore not possible. As a result, the hospital sampling taken as a basis here is somewhat larger than in section 4. But all ratios always refer to general hospitals. Purely psychiatric hospitals and purely day- and night hospitals as well as university hospitals are not included.

5.1 Efficiency

Key ratios on efficiency (Tables 4 to 11) point to higher profitability and investment capacity. This is seen in particular in the analysis of the financial ratios (Tables 10 and 11). Moreover, a higher labour productivity of private providers is observed, above all on a view of case-mix points per full-time employee (Table 4). Here it has to be pointed out that on average a full-time employee in privately owned

Source: RWI.

hospitals generates more revenue, i.e. more case-mix points, but at the same time does not really have more patients to care for. Table 7 also shows for nursing staff that their workload in private hospitals is not higher. The higher number of case-mix points per full-time employee stems from the higher average CMI of the private hospital operators.

Privately Owned Hospitals

5.2 Personnel

Private hospitals have a lower personnel cost share than other hospital operators, which is presumably partly explained by their higher rate of outsourcing and, by the same token, a higher share of material costs (see also section 4.2). Note that in the costs of medical doctors as a proportion of gross costs there are hardly any ownership-specific differences (Table 18).

5.3 Medical treatment

This section will use additional data to examine the question of whether the efficiency of privately owned hospitals is achieved to the detriment of medical care / quality. As it turns out, private hospitals by no means score worse in terms of the treatment of patients. On the one hand, the private hospitals treat an older and more complex type of patient, as revealed by a higher CMI. On the other hand, there are no significant differences in medical treatment compared with other hospital owners, for example in the percentage of caesarean sections (Table 20) or the percentage of stillborn children (Table 21). This result is seen in the selection of care hospitals carried out on the basis of FDZ data.

5.4 Societal aspects

To perform their tasks for society, hospital operators, in addition to providing medical care, also have a duty to make sparing use of public resources, to generate public resources through tax payments, and lastly to train specialist staff. The data reveal that private hospitals receive considerably fewer government grants but pay significantly more taxes than other hospital owners (cf. Table 10). In terms of training costs (Table 27), the private hospitals have a smaller share in gross costs than the other owners. However, this share has increased noticeably since 2002 while remaining constant with the other hospitals. In future – assuming a continuation of the trend and an increasing shortage of specialist staff – it is likely to reach the level of the other hospitals.

Source: RWI; Statistisches Bundesamt (Grunddaten). -As of 2002 the following large medical technology units were captured: Digital subtraction angiography (DSA), scintillation cameras, life support machines and dialysis machines.

5.5 Available capacities

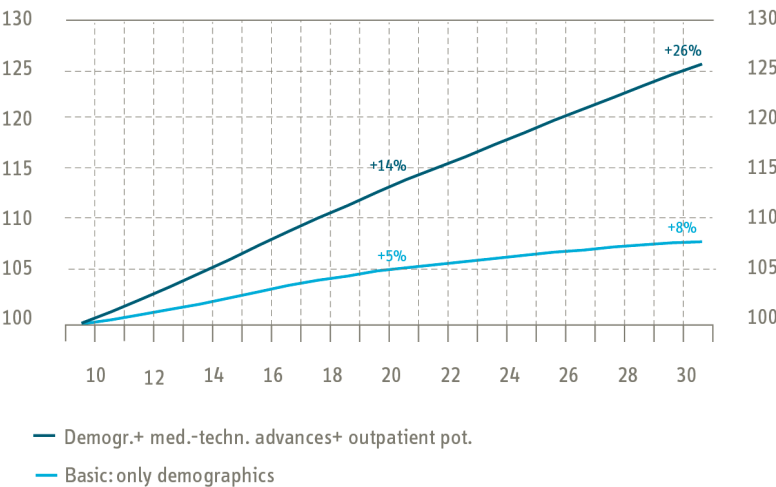

Sections 4.4 and 4.6 have already shown in an impressive manner that privately owned hospitals participate in making available medical infrastructure to secure generalised hospital care delivery meeting the needs of patients. This is demonstrated once again impressively by the following table of the number of intensive care beds per 100 beds (Table 28) and the number of large medical technology units per 1,000 beds (Table 29) over time. Lastly, the higher investment ratio of the private hospital operators shows that they invest much more in infrastructure than the other operators (cf. Table 11).

6. Outlook

As a result of demographic trends, the potential of the German hospital market will see further growth. That said, it is hard to make a forecast on how the number of cases will develop up to the year 2030. This is something RWI looked at in its 2011 Hospital Rating Report. Based on the demographic trend at the district level, trends in the prevalence rates in the past years, and subject to assumptions on

6. Outlook

Diagram 32
Projection of number of cases
 2009 to 2030; 2009=100

Source: ADMED, HCB, RWI; FDZ (2011).

outpatient potential, the number of inpatient cases was extrapolated to 2030. For this purpose, based on the regional use of hospitals in 2008, the regional prevalence rates (inpatient cases per inhabitant) per ICD, age and gender were determined. Taking account of the trend in prevalence rates – possibly caused by advances in medical technology – and outpatient potential, RWI expects to see about 14% more cases nationally by 2020 than in 2009. This corresponds to a average annual increase by roughly 1.2% and would translate into a total increase of 26% by 2030. Assuming constant prevalence rates, the rise would be roughly 6% or 0.5% p.a. by 2020 (Diagram 32).

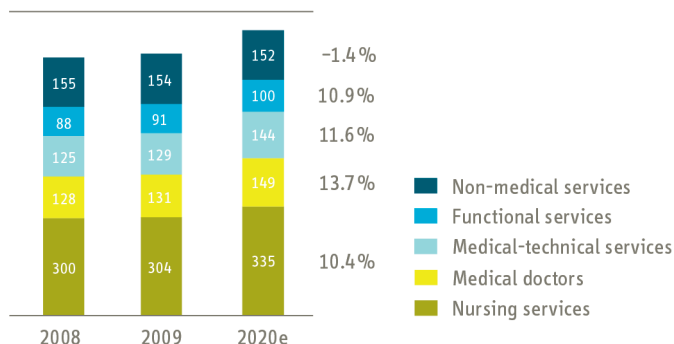

This shows that the hospital market will continue to be a demand-driven growth market in future as well. Increasingly, however, not only inpatient cases but also outpatient service volumes will play an important role in and at the hospital. This shows all the more that it will be decisive for hospital operators to adjust to the new framework conditions in good time and to prepare themselves for the changing demand with investments, optimised processes as well as adjustments in the structures of service volumes. That will call for a great deal of entrepreneurial savvy and good management as well as investment capital.

Privately Owned Hospitals

Diagram 33

Expected staff requirement

2008 to 2020; in 1 000 full-time employees

Source: RWI; Statistisches Bundesamt (Grunddaten); Werblow and Schoffer (2010).

In addition, one of the big challenges for all hospital owners will be how to recruit qualified specialist staff. For example, the demographic transformation is resulting in higher demand for healthcare services. At the same time the population on average is greying as fewer persons in employment are expected. Here, too, RWI has estimated personnel requirements up to the year 2020 in its 2011 Hospital Rating Report (Diagram 33).

This forecast is made on the basis of the expected number of cases in the scenario of demographic change, growing prevalence numbers and outpatient potential, the change in duration of stay and a constant level of outsourcing. In 2020, RWI estimates overall a 9% higher personnel requirement than in 2009, which, however, is much higher for medical doctors and is in decline for non-medical services. This increasing shortage of personnel in future will confront hospital owners with huge challenges, both in the area of recruiting and with reference to the expected increase in personnel costs overall.

For medical doctors and non-medical services, the assumption is for considerable wage increases. In principle, these will probably be higher for medical doctors given their greater shortage as compared with the area of non-medical services. For medical doctors, Augurzky et al. (2011) have assumed wage increases to the tune of 3.0% p.a. in 2010 and 2011 and of 2.8% p.a. from 2012. For the area of non-medical services, wages have been expected to climb by 2.5% in each of 2010 and 2011 and 2.2% p.a. from 2012. Also changes in non-wage labour costs were

6. Outlook

Diagram 34

Expected costs per full-time employee

2002 to 2020; 2009 = 100

Source: RWI; Statistisches Bundesamt (2011: Verzeichnis).

taken into account, which stood at 38.7% in 2010 and could rise to 40.6% by 2020. Under these assumptions, total costs per full-time employees are the most pronounced for doctors at 37%, and for non-medical services is 29% (Diagram 34). If the volume and price effects are combined, total personnel costs rise by 44% or 3.4% p.a. between 2009 and 2020.

Against this background two things become clear: first, it will be essential for hospitals in future to ensure attractive workplaces if they want to recruit and retain staff. Second, it will be decisive to make sparing use of dear human resources. This is an area in which the private hospitals appear to be already one step ahead of the non-private ones.

Privately Owned Hospitals

Glossary

BDPK	Federal Association of Private Hospitals in Germany (<i>Bundesverband Deutscher Privatkliniken e.V.</i>)
BQS	Federal Agency for Quality Assurance (<i>Bundesgeschäftsstelle für Qualitätssicherung</i>)
Cash Flow	The monies available to a business. In this Study, we calculate cash flow as net profit plus depreciation on assets financed from own funds
CM	Case mix - Total of all relative weightings of DRGs performed in a hospital
CMI	Case mix index - average relative weighting of a hospital or specialist department: case mix divided by the number of cases
DKG	German Hospital Association (<i>Deutsche Krankenhausgesellschaft</i>)
DRG	Diagnosis related groups - remuneration-uniform case groups to which each case is attributed depending on diagnoses and the procedures performed. In 2012, 1,193 different DRGs are available. Each DRG has a relative weighting that is the same in every hospital throughout Germany
EBITDA	Earnings before interest, taxes, depreciation, and amortization - this is operating earnings, i.e. revenue after deducting personnel and material costs. It is a business ratio that provides a relatively good approximation of a company's cash flow. EBITDA margin
EBITDAR	Earnings before interest, taxes, depreciation, amortization and rents
Equity ratio	Equity capital divided by balance sheet total
Equity ratio with special item	Equity capital including special item divided by balance sheet total
FDZ	Research Data Center of the State Statistical Offices (<i>Forschungsdatenzentrum der Statistischen Landesämter</i>)
FT	Full-time employee
GDP	Gross domestic product

Glossary

HGB	German Commercial Code (<i>Handelsgesetzbuch</i>)
HGB balance sheets	Income is equal to sales plus other operating income
ICD	International Statistical Classification of Diseases
Income	Total of revenue income, changes in holdings, recognised own services and other operating income
KHG	Hospital Financing Act (<i>Krankenhausfinanzierungsgesetz</i>)
Material costs	Material expenditure (consumables and supplies, merchandise and services)
Non-p.	Non-profit
P&L	Profit and loss statement (also known as income statement) - list of a company's expenditures and income for a certain period, normally a financial year
Personnel costs	Total of gross wages and salaries, social security contributions, pension expenditures
Probability of default	Probability of occurrence of a credit default, as a rule with reference to a 1-year horizon.
Rating	To assess a debtor's solvency, rating classes are formed. A debtor is assigned to a category in a bank-internal rating according to bank-internal criteria, and with internationally operating rating agencies such as Moody's, Standard & Poor's or Fitch the assignment is effected following a comprehensive assessment of the company
Relative weighting	Weighting of a DRG under the remuneration system based on DRG case flat rates; the remuneration of a DRG is obtained by multiplying its relative weighting and base rate
SGB	German Social Insurance Code (<i>Sozialgesetzbuch</i>)
SHI	Statutory health insurance
Special item ratio	Special item divided by balance sheet total
TK	<i>Techniker Krankenkasse</i>
WiDO	Research Institute of the AOK (<i>Wissenschaftliches Institut der AOK</i>)

Privately Owned Hospitals
