Do new opportunities arise for women in post-war countries? 
The case of Rwanda

Violent conflict is a severe obstacle for economic development and poverty alleviation. It harms humans and destroys physical property. However, conflict may also trigger social change. This contribution discusses how women may assume new economic responsibilities in a post-conflict environment.¹ The analysis focuses on the case of Rwanda, a small landlocked nation in Central Africa that erupted into genocide in 1994. During the genocide, more men than women died, which caused a shortage of men in the post-genocide period. It is shown that the genocide affected women in different ways. Many widows became breadwinners of their household and took on new economic activities. In contrast, both wives and unmarried women conform to the traditional female gender ideal. This may be a strategy to improve their chances of getting married.

Rwanda has a long history of violent conflict. The German colonial administration and later the Belgians (who replaced the Germans after WWI and ruled Rwanda until 1962) fueled tensions between the two largest ethnic groups, Hutu (the majority) and Tutsi (the minority). After Rwanda became independent in 1962 under a Hutu-led government, Tutsi were attacked during several outbreaks of ethnic violence. The conflict peaked in 1994, when extremist Hutu militia known as Interahamwe, the Rwandan Armed Forces and Rwandan police forces committed genocide against the Tutsi minority. To a lesser degree, moderate Hutu intellectuals were also targeted.² This was one of the most devastating violent conflicts since the end of the Cold War.

Within just 100 days, between 500,000 and 1 million individuals were massacred, approximately 10 percent of Rwanda’s population.³ Moreover, more men and boys than women and girls died, which resulted in a shortage of men in the post-genocide

¹ The research underlying this Weekly Report has been supported by the United States Institute of Peace (USIP). The opinions, findings, and conclusions or recommendations expressed in this publication are those of the author and do not necessarily reflect the views of USIP.
The sex ratio (the ratio of males to females) dropped sharply for cohorts born before 1983 (Figure 1), due to targeted violence against men. The decrease in the sex ratio of cohorts born before 1948 may indicate lower overall life expectancy of men, even prior to the genocide.

In short, the genocide severely altered the demographic structure of Rwandan society. On the one hand, it left many women without partners. The number of widows, of unmarried, and of divorced women rose sharply in the aftermath of the genocide. Between 1992 and 2000, the proportion of female-headed households increased from 19 percent to 37 percent. On the other hand, the shortage of men has severe socio-economic implications. Many women suddenly became household head. This challenges the cultural ideal that assigns women in Rwanda the role of caregiver and men as breadwinners in households.

My research analyzes the impact of the genocide on the division of labor within households in post-genocide Rwanda. I do so by examining how men and women spend their time on domestic and income-generating activities. In other words, how did gender-specific household tasks change after the Rwandan society was struck by the genocide?

Women have higher work burdens than men

The data base for this research is a large household survey, the Enquête Intégrale sur les Conditions de Vie de Ménage (EICV), collected by the National Institute of Statistics of Rwanda in 2005/2006. The

Do new opportunities arise for women in post-war countries?

EICV survey comprises a sample of 6,900 households which are representative of all Rwandan provinces.8 Detailed information was recorded on all household members and their socio-economic characteristics, such as age, health, education, and civil status as well as household ownership of assets, economic activities, and time use.9

Women and men in rural Rwanda spend their time very differently (Table 1). For example, the wife of a household head works on average 24.3 hours per week in domestic tasks within the household, such as cooking, cleaning, and childcare. In contrast, a male head of household spends on average almost 18 hours per week less in these tasks than his wife. However, the opposite is true for income-earning activities. In both agricultural wage work and non-farm market work, such as civil service or trading in the local market, men are engaged more intensively than their wives. Farm labor on the household’s property (mostly this relates to growing food crops for household consumption) is shared equally by wives and husbands, with each one working about 22 hours per week.

The same pattern in the division of labor—female caregivers, male breadwinners, and equal work shares in subsistence farming—is present when one compares the time use of teenage girls and teenage boys or of other adult female and adult male household members (for instance, the parents of the head of household). Importantly, wives, teenage girls, and other adult female members have greater total work burdens than their male counterparts.

Widows have a particular status

Widows10 spend their time differently, inconsistent from the gendered division of labor apparent in households consisting of a husband, a wife, and children. Compared to such “typical” households, a widow household head spends on average 13.5 hours per week more on domestic tasks than a male household head (Table 2). At the same time, she works 7.5 hours less in income-earning activities. Hence, her time use differs from a typical male household head. Yet a widow who is head of household engages in domestic tasks to a lesser extent than a wife (Table 1). In short, the time use of widows leading a household falls in-between the typical caregiver role of a wife and the breadwinner role of a male head of household. It appears as if widows perform both roles—at least to some extent—simultaneously.

Interestingly, in widow-headed households, not only is the time use of the widow head different, but also that of other household members, such as children and siblings of the head, is different (Table 2). Female household members living in widow-headed households work less in domestic tasks than those living in male-headed households. Male household members living in widow-headed households work less in income-generating activities than their counterparts living in male-headed households. This is surprising: Given that a widow head on average earns less than a male head in Rwanda, one would expect that male members would be required to help as secondary laborers.11

10 The EICV survey does not record the husband’s date of death or cause of death. Hence it is not possible to distinguish between war widows and other types of widows (for instance, AIDS widows). Yet, given the high conflict-related mortality of men, it is very likely that the majority of widows lost their husband during the genocide.

11 There is evidence from Mexico showing that men in female-headed households work harder in order to compensate for the gender wage

---

8 In the following, the analysis focuses on rural areas only.

9 Time use is a relatively new field of research in development economics. It has recently been acknowledged that individuals can be poor in terms of income and ownership of assets, but also in terms of time. See, for instance, Blackden, M.C., Wodon, Q. (Eds): Gender, time use, and poverty in Sub-Saharan Africa. World Bank Working Paper, 73, 2006.
Economic necessity drives women to become breadwinners

So far the evidence discussed only differentiates time use by a person’s gender and position within the household. Do wives work less in the market sector than their husbands because they have less education? Are widows spending less time on domestic tasks than wives because they have fewer children to take care of? A multivariate econometric analysis is conducted in order to account for the fact that persons and households differ in their endowments, such as education, age, wealth, and household size. Such an analysis allows a better grasp of the drivers behind the gendered division of labor. The econometric analysis has three key findings.

First, different factors determine who does what in different types of households. Households characterized by a traditional composition—a male head, his wife, children—stick to traditional gender roles. In these households, women engage in domestic tasks and farming, even when their education and skills are accounted for. On the contrary, in widow-headed households, gender roles matter less for the division of labor. In particular, widows engage more intensely in income-generating activities than married women. Hence, it seems that restrictive female gender roles within the household are mitigated by war-induced changes in household composition. Many widows are forced to assume the role of the breadwinner, and take over the role of the principal decision-maker in their household from their deceased husband.

Second, it may be a plausible hypothesis that a person’s reputation and standing in the community is shaped by the extent that the person conforms to his or her gender role. This would imply that gender roles have a stronger impact on activities that take place in public (that is, visible to neighbors) than those carried out inside the homestead. Yet results from the econometric analysis do not support this hypothesis: Gender roles have a similar impact on activities in different spheres. Men and women comply to gender roles, both in the home (what makes cooking, for instance, a female household chore), and in activities that are performed in public (such as buying supplies in the market as a male task). The degree of visibility of an activity to community members does not influence how men and women share their work.

Third, the availability of potential partners on the marriage market has a strong impact on individuals’ time use patterns. Women work more intensively in “typical” female activities if they live in a region with an extreme shortage of marriageable men of similar age. This effect is particularly strong for young, unmarried women who will eventually marry and leave the household. For these women, closely following the Rwandese female ideal of a caregiver may be a strategy to improve their standing on the marriage market.

Conclusions

The 1994 genocide in Rwanda affected and still affects women in various ways. For married women, little has changed: they continue to take care of domestic tasks in their household and subsistence farming. Young unmarried women work intensively in typical female activities. However, unmarried women face a shortage of potential partners of similar age on the marriage market. This may be a reason why these women conform more closely than other women to the ideal female role in Rwanda. Yet new economic opportunities arise to widows. They engage more intensively in income-generating activities than other women. However, from the perspective of the widows themselves, their larger economic responsibility may be driven by the necessity to replace the economic contribution of their deceased husband. From a macroeconomic perspective, the more active engagement of (at least some) women in gainful employment is beneficial to Rwanda’s economy: The stock of labor, skills and talent increases.

To conclude, there is no evidence that the genocide led to a more flexible division of domestic and paid labor per se. Rather, it seems that roles and responsibilities within widow-headed households were rearranged to cope with the absence of the male breadwinner. In this regard, widows in Rwanda have much in common with Trümmerfrauen in Germany after WWII. It remains a topic for future research to explore the possible lasting impacts of the outlined mechanisms on gender roles in the cohort of children born after the genocide that no longer suffers from unbalanced sex ratios.

13 To approximate the marriage market, sex ratios in a person’s potential cohort of partners in a given province are calculated from census data.
