Any opinions expressed here are those of the author(s) and not those of IZA. Research published in this series may include views on policy, but the institute itself takes no institutional policy positions.

The Institute for the Study of Labor (IZA) in Bonn is a local and virtual international research center and a place of communication between science, politics and business. IZA is an independent nonprofit organization supported by Deutsche Post Foundation. The center is associated with the University of Bonn and offers a stimulating research environment through its international network, workshops and conferences, data service, project support, research visits and doctoral program. IZA engages in (i) original and internationally competitive research in all fields of labor economics, (ii) development of policy concepts, and (iii) dissemination of research results and concepts to the interested public.

IZA Discussion Papers often represent preliminary work and are circulated to encourage discussion. Citation of such a paper should account for its provisional character. A revised version may be available directly from the author.

ABSTRACT

Migration, Openness and the Global Preconditions of *'Smart Development'*

In this article, we present a first empirical reflection on 'smart development', its measurement, possible 'drivers' and 'bottlenecks'. We first provide cross-national data on how much ecological footprint is used in the nations of the world system to 'deliver' a given amount of democracy, economic growth, gender equality, human development, research and development, and social cohesion. To this end, we first developed UNDP-type performance indicators on these six main dimensions of development and on their combined performance. We then show the non-linear regression trade-offs between ecological footprints per capita on these six dimensions of development and their combined performance index. The residuals from these regressions are our new measures of smart development: a country experiences smart development, if it achieves a maximum of development with a minimum of ecological footprint. We then look at the cross-national drivers and bottlenecks of this 'smart development' and compare their predictive power using stepwise regression procedures. Apart from important variables and indicators, derived from sociological dependency and world systems theories, we also test the predictive power of several other predictors as well. Our estimates underline the enormous importance of the transfer of resources from the center to the periphery, brought about by migration, with huge statistical observed positive effects of received worker remittances on smart human development, Happy Life Years, smart gender justice, smart R&D, and both formulations of the smart development index.

JEL Classification: C43, F22, F24, Q56

Keywords: index numbers and aggregation, environment and development, environment and trade, smart development, sustainability, environmental accounts and accounting, environmental equity, population growth, international migration, remittances

1. Introduction

In this article, we present a first empirical reflection on '*smart development*', and its measurement and its possible 'drivers' and 'bottlenecks'. The very idea of '*smart development*' was first proposed by Meadows (1992) and has not been really followed up to now in social science ever since. In the face of the huge usage of this term in the international media, such a statement is perhaps surprising, but our verdict corresponds to the clear bibliographical evidence on the base of such indices as '*ISI Web of Knowledge*' or '*Cambridge Scientific Abstracts*'.

The basic idea, proposed by Meadows two decades ago in his single pioneering article on the issue was that we should relate our whole concept of development, and not just economic growth, to the natural resources needed to sustain it. In a similar vein, the Happy Planet Organization presented the so-called 'Happy Planet Index' (HPI), which is, as it is perhaps known to the readership of this publication, an index of measuring the trade-off between ecological footprint data and life quality (Happy Life Years, HLYE). Arguably, ecological footprint today is the best single international yardstick for environmental destruction in a nation (see also York, Rosa, and Dietz, 2003).

Economic theory, for sure, is conscious about the non-linearity of the trade-off between income and happiness, with rising income levels not necessarily increasing the happiness of all. This phenomenon has become widely known in the economic research literature as the '*Easterlin paradoxon*' (Easterlin, 1995, 2001; Frey and Stutzer, 2002; Oswald, 1997; Stevenson and Wolfers, 2007). But here, we provide the first cross-national data, how much ecological footprint is used in the nations of the world system to 'deliver' a given amount of democracy, economic growth, gender equality, human development, research and development, and social cohesion.

To this end, we first developed UNDP-type performance indicators from current standard international comparative, cross-national social science data on the six main dimensions of development (democracy, economic growth, gender equality, human development, research and development, and social cohesion) and on the combined performance on these six dimensions (a kind of super-UNDP '*human development index*'). We then show the non-linear standard OLS regression trade-offs between ecological footprints per capita and their square on these six components of development and the overall super-UNDP development performance index, derived from them. The residuals from these regressions are our new measures of smart development: a country experiences smart development, if it achieves a maximum of democracy, economic growth, gender equality, human development, research and development, and social cohesion, and the combination of them with a minimum of ecological footprint.

We then look at the cross-national drivers and bottlenecks of this 'smart development', using standard comparative cross-national data, which operationalize standard economic, sociological and political science knowledge in international development accounting. We compare the predictive power of these standard predictors, using standard OLS stepwise regression procedures, based on IBM SPSS XVIII. Apart from important variables and indicators, derived from sociological dependency and world systems theories, we also test the predictive power of other predictors as well, ranging from geography and achieved development levels to the clash of civilization models,

feminist theories, migration theories, and the '*small is beautiful paradigm*' in the tradition of Schumacher.

In Section 2 we sketch a possible theoretical background. Section 3 will introduce the measurement concepts and the methodology of this essay. Section 4 will be dedicated to the presentation of the results on the drivers and bottlenecks of '*smart development*', while Section 5 will discuss the results in the framework of earlier theories and hitherto existing research, relevant for our subject. Section 6 presents our preliminary conclusions.

2. Theoretical background and earlier studies

To present a theory or competing theories of 'smart development' is virtually impossible, because there has been no measurement, let alone accounting of its cross-national successes and failures in the literature up to now. We are really had to start research into this issue from 'scratch'.

In this presentation of possible theories explaining 'smart development', we now should deal with the notion of '*openness*' or '*world economic openness*'. Among the studies, listed in international online-bibliographies as especially often being referred to, we find, among others, Alesina, Spolaore and Wacziarg, 2000; Dollar, 1992a and 1992b; Edwards, 1993; Frankel and Romer, 1999; Rodrik, 2006; Rodrik, Subramanian, and Trebbi, 2004; and World Bank, 2005. While Dollar's writings, widely disseminated around the globe, were especially straightforward in suggesting that a high share of exports and imports per GDP, and hence, an outward orientation of the society in question, is especially beneficial for economic growth and works in favor of the poorest strata of the population, the equally widely disseminated and received study by Frankel and Romer, 1999, comes to a more cautious conclusion: examining the correlation between trade and income one really cannot identify the direction of causation between the two. According to that study, countries' geographic characteristics, however, have important effects on trade, and are plausibly uncorrelated with other determinants of income. Frankel and Romer then construct measures of the geographic component of countries' trade, and use those measures to obtain instrumental variables estimating the effect of trade on income. Frankel and Romer suggest that trade has a quantitatively large and robust, though only moderately statistically significant positive effect on income. Rodrik, Subramanian, and Trebbi, 2004 further shattered the optimistic assumptions about the beneficial effects of world economic openness on development outcomes in their study about the respective contributions of institutions, geography, and trade in determining income levels around the world, using recently developed instrumental variables for institutions and trade. Their results indicate that '*the quality of institutions "trumps" everything else*' (Rodrik, Subramanian, and Trebbi, 2004). Once institutions are controlled for, conventional measures of geography have at best weak direct effects on incomes, although they have a strong indirect effect by influencing the quality of institutions. Similarly, once institutions are controlled for, trade is almost always insignificant, and often enters the income equation with the "wrong" (i.e., negative) sign. In his influential study, 2006, Rodrik even went so far as to fundamentally question the 'Washington Consensus' based on open markets, which featured so prominently in Dollar, 1992a and 1992b:

Table 1: Deconstructing the Washington Consensus of liberalization and openness

	Original Washington Consensus		Augmented Washington Consensus
1	Fiscal Discipline	11	Corporate governance
2	Reorientation of public expenditures	12	Anti-corruption
3	Tax reform	13	Flexible labor markets
4	Financial liberalization	14	WTO agreements
5	Unified and competitive exchange rates	15	Financial codes and standards
6	Trade liberalization	16	"Prudent" capital accounting
7	Openness to Direct Foreign Investment	17	Non-intermediate exchange rate regimes
8	Privatization	18	Independent central banks/inflation targeting
9	Deregulation	19	Social safety nets
10	Secure Property Rights	20	Targeted poverty reduction

Source: Rodrik, 2006, based on World Bank, 2005

Appendix Tables 1a and 1b highlight the theoretical dimensions of this research paper. Among the many existing theories, we highlight here especially migration and its possible links to ‘smart development’.

The **divisive issue of migration** equally divides opinions around the globe, and it also divides opinions among the global social science research community. Also, it must be mentioned in our theoretical survey. As it is well-known, migration is part and parcel of the ‘*four freedoms*’ of capitalism, besides the freedom of goods, services, and capital. It is only logical to treat its possible influence on ‘smart development’ immediately after dealing with the possible effects of ‘openness’. Migration might have a very big effect on ‘*smart development*’. Migration, after all, assures continued production and hence also pollution in the migration recipient countries, while worker remittances, sent from there to the migration sending countries, might contribute to overall consumption, well-being and investment in environmentally more sustainable housing and heating systems in the migration sending nations. A flagship survey of the hitherto existing migration theories (Masey et al., 1993) came to the pessimistic conclusion that migration theories up to that time were either advanced to explain the initiation of international migration or put forth to account for the persistence of migration across space and time. Masey et al. suggested that, because they are specified at such different levels of analysis, the theories are not inherently logically inconsistent.

As **Taylor** pointed out in his summarizing policy statement on the state of migration theory for the United Nations in 2006, indeed it would be foolish to exclude migration from any future discourse about global development: The number of international migrants has increased more or less linearly over the past 40 years, from an estimated 76 million in 1965 to 188 million in 2005. The flow of international migrant remittances has increased more rapidly than the number of international migrants, from an estimated US\$2 billion in 1970 to US\$216 in 2004. Nearly 70% of all remittances go to LDCs. Remittances were equivalent to 78% of the total value of exports in El Salvador and 108% in Nicaragua. As Taylor also pointed out in a number of other studies, especially in 1999, worker remittances are especially affecting the less developed sending countries by the multiplier effect, well-known in economics since the days of John Maynard Keynes (Taylor, 2006: 9). The optimistic view about worker

remittances is also supported in the well-received comparative international study by Ziesemer, 2009: in this analysis, the author shows with pooled data for four different samples of countries receiving remittances in 2003 that the countries with per capita income below \$1,200 benefit most from remittances in the long run because they have the largest impact of remittances on savings. Their changes in remittances account for about 2% of the steady-state level of GDP per capita when compared to the counterfactual of having no changes of remittances. Their ratio of the steady-state growth rates with and without changes of remittances is 1.39. As savings react much more strongly than investment, an important benefit of remittances is that less debt is incurred and less debt service is paid than without remittances. All these effects are much weaker for the richer countries.

The **UNDP HDR 2009** edition maintains that financial remittances are vital in improving the livelihoods of millions of people in developing countries. There is a positive contribution of international remittances to household welfare, nutrition, food, health and living conditions in places of origin. Even those whose movement was driven by conflict can be net remitters, as illustrated in history by Bosnia and Herzegovina, Guinea-Bissau, Nicaragua, Tajikistan and Uganda, where remittances helped entire war-affected communities to survive. In some international migration corridors, money transfer costs have tended to fall over time, with obvious benefits for those sending and receiving remittances. Recent innovations have also seen significant falls in costs at the national level. With the reduction in money transfer costs, families who once relied on relatives and close family friends or who used informal avenues such as the local bus driver to remit are now opting to send money through banks, money transfer companies and even via cell-phones. An important function of remittances is to diversify sources of income and to cushion families against setbacks such as illness or larger shocks caused by economic downturns, political conflicts or climatic vagaries (UNDP HDR, 2009: 72).

Similarly, the UNDP also maintains that there should be significant aggregate gains from movement, both to movers and to destination countries. The destination countries will capture about one-fifth of the gains from a 5% increase in the number of migrants in developed countries, amounting to US\$ 190 billion dollars. Immigration increases employment, with no evidence of crowding out of locals, and investment also responds vigorously to immigration. Population growth due to migration increases real GDP per capita in the short run, one-for-one (meaning that a 1% increase in population due to migration increases GDP by 1%).

Migrants bring broader economic benefits, including higher rates of innovation. Data from the United States show that between 1950 and 2000, skilled migrants boosted innovation: a 1.3% increase in the share of migrant university graduates increased the number of patents issued per capita by a massive 15%, with marked contributions from science and engineering graduates and without any adverse effects on the innovative activity of local people. The United States, in particular, has been able to attract migrant talent through the quality of its universities and research fund and infrastructure and its favorable patenting rules. In Ireland and the United Kingdom the share of migrants with tertiary education exceeds 30%, while in Austria, Italy and Poland it is below 15%. Countries offering more flexible entry regimes and more promising long-term opportunities have done better in attracting skilled people, whereas restrictions on duration of stay, visa conditions and career development, as in

Germany for example, limit uptake. The aggregate effect of immigration on the wages of local workers may be positive or negative but is fairly small in the short and long run. In Europe, both multi- and single-country studies find little or no impact of migration on the average wages of local people (UNDP, HDR, 2009: 84-85).

Summing up the debate, we should quote from the findings of Jeffrey Williamson, 2002: mass migration made an important contribution to late nineteenth century convergence in the 'North.' In the absence of mass migration, real wage dispersion would have increased by 7%, rather than decreased by 28%, as it did in fact. GDP per capita dispersion would also have decreased by only 9%, rather than by 18% as it did in fact. Wage gaps between New World and Old would have risen to 128% in 1910 when in fact they declined from 108 to 85%. Real wage convergence before World War I was attributable to migration, about two-thirds of the GDP per worker convergence, and perhaps one half of the GDP per capita convergence. There was an additional and even more powerful effect of the mass migrations on global income distribution. The 60 million European migrants before World War I came from countries whose average real wages and average GDP per worker were perhaps only half of those in the receiving countries. These migrant gains were an important part of the net equalizing effect on world incomes of the mass migrations. North-North mass migrations had a strong leveling influence in the world economy up to 1913. They made it possible for poor migrants to improve the living standards for themselves and their children. It also lowered the scarcity of resident New World labor which competed with the immigrants, while it raised the scarcity of the poor European labor that stayed home (whose incomes were augmented still further by emigrant remittances). South-South migrations were about the same size as the North-North flows.

Sanderson, 2010, was one of the first consistent research attempts to bring in migration as a determining variable of social well-being. Contemporary levels of international migration in less-developed countries are raising new and important questions regarding the consequences of immigration for human welfare and well-being. However, there is little systematic cross-national evidence of how international migration affects human development levels in migrant-receiving countries in the less-developed world. The Sanderson paper addresses this gap in the literature by assessing the impact of cumulative international migration flows on the human development index, the composite, well-known UNDP measure of aggregate well-being. A series of panel data models are estimated using a sample of less-developed countries for the period, 1970-2005. The results indicate that higher levels of international migration are associated with lower scores on the human development index, net of controls, but that the effect of international migration is relatively small.

In terms of thoroughly tested scientific knowledge, based on large-scale, cross-national empirical evidence, the next possible alternative theoretical tradition to fill the explanatory gap for 'smart development' accounting, coming to one's mind, would be **dependency and world systems theory**. Although its effect on the mainstream economic scholarly journals has been marginal, it had a very wide impact on the leading international sociological and political journals¹. Reasons of space do not

¹ International quantitative bibliometrical data on the impact of scholarly journals, i.e. the frequency and structure of the references in the international literature, are now available from such indices as SCIMAGO (<http://www.scimagojr.com/>, based on SCIVERSE-SCOPUS), ISI Web of Knowledge

permit us to debate at greater length this very vast sociological, political science and economic theory literature, centered on the subject of MNC (multinational corporation) penetration and economic and social development. We should rather concentrate, first of all, on what was actually predicted in the Bornschier/Chase-Dunn/Rubinson study, 1978, which must be regarded as the most often quoted flagship study of empirical dependency theory, analyzing the effects of MNC penetration on economic growth and income inequality²:

'(1) The effect of direct foreign investment and aid has been to increase economic inequality within countries. (2) Flows of direct foreign investment and aid have had a short-term effect of increasing the relative rate of economic growth of countries. (3) Stocks of direct foreign investment and aid have had the cumulative, long-term effect of decreasing the relative rate of economic growth of countries. (4) This relationship has been conditional on the level of development of countries. The stocks of foreign investment and aid have had negative effects in both richer and poorer developing countries, but the effect is much stronger within the richer than the poorer ones. (5) These relationships hold independently of geographical area.' (Bornschier/Chase-Dunn/Rubinson, 1978: 651)

Important later tests of these hypotheses, taking into account the most important control variables, like initial income levels³, could nothing but support and refine the original argument, independently from the research design for different indicators, time periods, samples and methods (see *inter alia* and to mention but a few studies: Beer, 1999; Bornschier, 1982, 2002; Dutt, 1997; Heshmati, 2006b; Kentor, 1998; Klitgaard and Fedderke, 1995; Tausch, 2003; Tausch and Prager, 1993; Tsai 1995).

Centre-periphery models in the tradition of Prebisch, 1950, 1983, 1988, and the proper 'dependency theories' in the tradition of such authors as Cardoso, 1977, 1979, Cardoso/Faletto, 1971, Furtado, 1963, 1964, 1976, 1983, Sunkel, 1966, 1973, 1978, and the quantitative research inspired by these theories, namely by Galtung, 1971, Sunkel, 1973 and later Chase-Dunn, 1975, Bornschier/Chase-Dunn/Rubinson, 1978 and Bornschier/Ballmer-Cao, 1979 all can be important elements in the debate about 'smart development'. All these theories claimed that the relations of dependency block long-run economic growth and bring about a socially unbalanced development, short spurts of economic growth notwithstanding.

There was a real 'growth industry' of blossoming and booming dependency - and world-system oriented studies of environmental problems during the last years. It has become really fashionable in many traditions of sociology and political science to blame the lack of 'sustainable development' on globalization and the workings of global capitalism, perceived as a center-periphery system. The central question, posed by Meadows, 1992, and by the Happy Planet Index methodology is not how much deforestation, ecological destruction etc. we face in the world system at given levels of

(Reuters/Thomson <http://www.isiwebknowledge.com/>) and SCIVERSE-SCOPUS (Elsevier <http://www.hub.sciverse.com/action/home/proceed>), which are available on-line at major Universities and research centers around the globe.

² International quotation figures, based on ISI Web of Knowledge (Reuters/Thomson <http://www.isiwebknowledge.com/>).

³ Also conventional economic theory of growth accounting and income inequality accounting practices such controls. To treat properly what economists tend to call the convergence effects of poor countries growing faster than richer ones, see, among others, Barro, 2003.

development, but how much footprint was consumed in the nations of the world system to ‘deliver’ a given amount of development [democracy, economic growth, gender equality, human development, research and development, and social cohesion].

Nevertheless, the relatively coherent tendency of these studies, most notably Dick and Jorgenson, 2010; Jorgenson and Burns, 2007; Jorgenson, 2003; 2004a, 2004b; 2005; 2006a, 2006b; 2007a, 2007b; 2008; 2009a, 2009b; Jorgenson, and Burns, 2004; Jorgenson, Dick, and Mahutga, 2007; Jorgenson, Kuykendall, and Kennon 2008; Lawrence, 2009; Longo and York, 2008; Mostafa and Natarajan, 2009; Mostafa, 2010a, 2010b; Nugent, and Shandra, 2009; Shandra, 2007a, 2007b; Shandra, and London, 2008; Shandra, Leckband, and London, 2009; Shandra, Leckband, McKinney, and London 2009; Shandra, London, Whooley, and Williamson, 2004; and finally Shandra, Shor, and London, 2008, 2009 suggests that there seems to be a strong causal interaction between transnational capitalist penetration and environmental degradation, especially in third world countries. To date, the most important counter-study to this fledgling scientific tradition was the essay by Ehrhardt-Martinez, Crenshaw, and Jenkins, 2002, which analyzed deforestation rates 1980-1995 in the developing countries, using ordinary least squares regression. Net of controls for initial forest stock and the quality of deforestation estimates, the authors find strong evidence for an ‘**environmental Kuznets’ curve**⁴ driven by (1) agglomeration effects linked to the level of urbanization, (2) rural-to-urban migration that partially offsets rural population pressure, (3) the growth of services-dominated urban economies, and (4) strong democratic states. The authors find little evidence that foreign debt or export dependence influence the deforestation rate. Although deforestation continues to pose pressing and potentially irreversible environmental risks, there is evidence of self-corrective ecological and modernization processes inherent in development that act to mitigate these risks.

It is now time to present also some thoughts on the **other control variables** (see also Appendix Table 1a and 1b). A number of high-profile studies in economics have used such control variables, while the sociological profession seems to be more cautious about their use⁵. The Kuznets curve of economic inequality (Barro, 2000) or environmental degradation (Selden and Song, 1994; Stern, 2004; Stern, Common and Barboer, 1996) must be just as mentioned in this context as the study by Biswas and Ram, 1986 on military expenditures; Ram, 1997 on tropical climate; the sociological study by Crenshaw and Robison, on population, demography, pre-industrial heritage and socio-linguistic integration as factors of economic growth (see also the essays on demography, the economic size of nations, and geography (absolute latitude) into account - see also Easterly, 2000; Poe and Tate, 1994); Ram, 1986 on government expenditures; and the sociological essay by Scanlan, 2004, on women in government on food security and social development (see also UNDP, HDR, 1995; furthermore, from the ever more growing important perspective of feminism and good governance: Holmberg, Rothstein and Nasiritousi, 2009; Logo, 2008; Matt, 2010; McDowell, 1992; Rankin, 2002; Rothstein and Teorell; as well as the survey on women in government

⁴ Put in easily understandable everyday language, the Kuznets curve rests on the idea, proposed by Kuznets, 1955, that developmental outcomes (like inequality) are a non-linear function of development levels

⁵ Interested readers are also referred to Easterly, 2000, 2002; Easterly and Levine, 1997; Heshmati and Tausch, 2007 for further reference.

and the welfare state in Orloff, 1996). We also should mention culture (membership of a country in the Islamic Conference; see the vast social science debate following Huntington, 1993; by contrast: Amin, 1997). A non-exhaustive more detailed account of earlier important studies is given in Table 1b of the Appendix of this paper.

Confronted with all this startling variety of contradictory statements on the drivers and bottlenecks of international development, we now should present a survey of the empirical methods used in this study.

3. Methods and measurement

To start with, we have made our data for our calculations completely and freely available on the Internet, so that the global research community can have free access to the original data and the opportunity to check our results or to conduct new research (<http://www.hichemkaroui.com/?p=2017>). This internet site offers not only the Microsoft EXCEL data (Table 1 of the EXCEL file) and a list of the sources (Table 2 of the EXCEL file), but also a codebook in PDF format. A brief description of the smart development data, calculated from that data source, is also contained in the Appendix Table 4 of this work.

Our investigation duly acknowledges many of the key determinants of economic growth, mentioned in the economic literature, like current shares of the country's inhabitants in total world population, calculated from UNDP data; the famous Heritage Foundation 2000 Economic Freedom Score; absolute geographical latitude, adapted from Easterly's growth theory; the UNDP figures for long-term annual population percentage growth rate, 1975-2005; the trade-off between development level and development performance, otherwise also known in economics as 'conditional convergence' ($\ln \text{GDP per capita}$; $\ln \text{GDP per capita}^2$); the simple Huntingtonian fact of whether a country is a Muslim country, to be measured by the Organization of Islamic Conference (OIC) Membership or by Muslim population share (Nationmaster); UNDP data on the simple geographical fact of population density (based on the CIA's World Fact book); UNDP data on public education expenditure per GDP; and the UNDP education index, combining the enrolment rates at the primary, secondary and tertiary education levels. We also take into account UNDP figures on military expenditures per GDP and the openly available CIA data on military personnel rate, which are key variables of contemporary political science international relations theory and peace research. In our analysis, we also show the theoretical and practical (political) potential of the following two drivers of development, which are somewhat a 'terra incognita Australis' in the hitherto existing macro-sociological debate, like migration and European (Monetary) Union membership.

To gain a real empirical knowledge under scrutiny here, we first developed UNDP-type indicators from current standard international comparative, cross-national social science data on six dimensions of development and on their combined performance. We then show the non-linear standard OLS regression trade-off between ecological footprint per capita and its square and these six dimensions of development (and the overall development performance) indices. The residuals from these regressions are our new measure of smart development: with a minimum of ecological footprint one has to achieve a maximum of democracy, or economic growth, or gender equality, or human

development, or research and development, or social cohesion (and the combination of all of them). We then look at the drivers and bottlenecks of smart development. Can the accumulated knowledge of cross-national development research be applied to this new question writing? We use standard comparative cross-national ‘development accounting’ data, which operationalize standard econometric drivers of economic growth, and compare their weight in explaining ‘smart development’ with the results for the clash of civilization models, political integration theories, feminist theories, migration theories, and peace research approaches to global development. We also analyze the possible explanatory weight of sociological dependency and world systems theories and later globalization critical research, and also do not overlook in our choice of independent variables with a possible effect on the dependent variables – smart development - the ‘*small is beautiful paradigm*’ in the tradition of Schumacher.

The choice of a country to be included in the final analysis (175 countries) was determined by the availability of a fairly good data series for these independent variables (if not mentioned otherwise, UNDP data for the middle of the first decade of the new millennium). In the final regressions, we applied the ‘list wise deletion of missing values’ routine (i.e. only entering countries with complete data into the statistical analysis).

The statistical design of our study is thus based on the usual, OLS standard regression analysis of the ‘**kitchen sink type**’ (Durlauf *et al.*, 2008; Hertz, Hebert, and Landon, 1994) of economic growth and economic, social and political performance in the research tradition of Barro, 2003.⁶ Surveying the vast econometric literature on the subject of the possible drivers and bottlenecks of the EU-2020 process and overall development performance of a given country, one indeed finds support for the inclusion of geographic and demographic variables in the comparative analysis of development success or failure. Our list is thus corresponding to international research standard praxis in the discipline of general ‘development accounting’ (Barro and Sala-i-Martin, 2003; Dixon, 1987; Dixon and Moon, 1986, 1989; Durlauf *et al.*, 2008; Fain, 1997; Fosu, 2009, 2010a, 2010b, 2010c; Moon and Dixon, 1992; Shandra, 2007a, 2007b; Shandra *et al.*, 2009; Tausch and Prager, 1993). Compared to a recent approach on the subject (Knight and Rosa, 2011), we do include globalization-oriented variables as well, and not just levels of GDP, winters, social trust, democracy, inequality, and Latin America, former USSR, Africa, and Asia as ‘dummy variables’ (Knight and Rosa, 2011). There is a wide and well-established research tradition in international comparative sociology to include globalization-related drivers of environmental decay (Jorgenson, 2008, 2009a, 2009b, 2009c, 2009d). To exclude such variables and to introduce instead four geographically determined dummy variables (Latin America, former USSR, Africa, and Asia, as was done by Knight and Rosa, 2011) does not necessarily increase the theoretical and predictive power of analysis.

The statistical design of our study is based on the usual, SPSS-PAWS XVIII⁷ ordinary least square standard regression of the ‘kitchen sink type’. The term was re-introduced in more recent standard social science journal vocabulary in Laver and Shepsle, 1999.

⁶ To our knowledge, the term ‘kitchen sink regression’, commonly used in econometrics of economic growth, was re-introduced in more recent standard social science journal vocabulary in Laver and Shepsle, 1999.

⁷ <http://www-01.ibm.com/software/analytics/spss/products/statistics/>

Prior stepwise regression procedures selected the significant among the total list of 26 available predictors. Among the many international studies, applying such a research design, we find Hertz, Hebert, and Landon, 1994. This study analyzed the effects of independent variables including dietary factors, medical resource availability, gross national product (GNP/capita), literacy rates, growth in the labor force, and provision of sanitation facilities and safe water on infant and maternal mortality rates and life expectancy at birth. The study fitted a series of general linear models for each of the three dependent variables⁸.

Since our article does not feature primarily on ecological footprint, but on a variety of measures of ‘smart development’, which are mathematically derived from the logic of the Happy Planet Index (see also Ng, 2008a and 2008b; Veenhoven, 1996), it suffices to say here that ecological footprint (g ha /cap)⁹, is indeed a one-catch all-indicator of ecological strain, caused by human activity. Ecological footprint and its measurement cannot be further debated in the framework of article and at this stage must be regarded as a ‘given’ (for studies about the logic and determinants of footprint per capita see also Dietz *et al.*, 2007 and 2009). It should be enough to state here that it is measure of the amount of land required to provide for all their resource requirements plus the amount of vegetated land required to sequester (absorb) all their CO2 emissions and the CO2 emissions embodied in the products individuals consume. This figure is expressed in units of ‘global hectares’. In 2005, the per capita footprint for the rich OECD nations was 6.0 global hectares¹⁰. The other variables are then compared to the footprint, which was used by a society to achieve a given standard of democracy, economic growth, gender equality, human development, research and development, and social cohesion. We should also remind our readers here of the fact that the Happy Planet Index Organization measures the Happy Planet Index on the basis of the global life satisfaction (Happy Life Years), which have to be maximized in relationship to the ‘ecological price’ of happiness, ecological footprint.

It is then of course very tempting to calculate – in a Schumacherian tradition – the ‘environmental price’ of different development processes, like democracy, economic growth, gender equality, human development, research and development, and social cohesion. The Happy Planet Organization calculates the HPI in the following way:

$$(1) \quad HPI_i = ((HLYE_i)/(EFPC_i + \alpha)) \times \beta$$

where Happy Life Years (HLYE) is obtained as the product of life expectancy (LE) and average life satisfaction (LS) index. In its currently used formula, the Happy Planet Organization adds a constant (α) to ecological footprint. The result of the division: [Happy Life Years divided by Ecological Footprint plus the constant (α)] is then multiplied by another, equally arbitrarily chosen constant (β) to normalize the efficiency index. In the Happy Planet Organization formula, the constants have the following numerical values: (α) = 3.35 and (β) = 6.42.

⁸ It emerged that the per cent of households without sanitation facilities showed the strongest association with all three dependent variables: life expectancy at birth, infant mortality rate, and maternal mortality rate

⁹ <http://www.footprintnetwork.org/en/index.php/GFN/>

¹⁰ <http://www.happyplanetindex.org/>

The highest global HPI score is that of Costa Rica (76.1 out of 100). Of the 10 best performing countries of the world, nine are in Latin America.¹¹ But unfortunately, the Happy Planet Organization’s straightforward and simple methodology overlooks advances in the social sciences, which long ago already developed appropriate methodologies to relate life quality variables – like life expectancy – to GDP per capita or energy consumption levels in empirical, and non-linear mathematical formulations. The latter captures much better than the above simple equation the underlying non-linear tradeoffs between ‘energy consumption and/or environmental strain’ and ‘life quality’ (Goldstein, 1985). Goldstein’s empirically developed idea that basic human needs indicators – like life expectancy – are a non-linear function of development levels has been so widely received in the social science literature that it has become a real international standard nowadays (see Afxentiou, 1990a, 1990b; Anand and Ravillion, 1993; Anson, 1988, 1991; Cheng, 1989; Dixon, 1987; Dixon and Moon, 1986, 1989; Fosu, 2009, 2010a, 2010b, 2010c; Kakwani, 1993, 1995; Khan, 1991; King, 1998; Knight and Rosa, 2011; Mazumdar, 1996, 2000; Moon and Dixon, 1992; Newman and Thomson, 1989; Rudra, 2009; Tausch and Prager, 1993). The neglect of such a basic non-linear function (whatever its concrete mathematical formulation¹²) is a major shortcoming of the currently used Happy Planet Index calculation. The global public health research tradition, too, produced massive evidence on the cross-national determinants of life expectancy and other life quality variables (to quote but a few studies: Wilkinson, 1992; Wilkinson and Pickett, 2006; Tausch, 2010). This growing methodological convergence of the social sciences, geography and earth sciences, and public health research on predictors of life quality at different stages of development should be taken into account in this article (Fain, et al. 1997; Mostafa, 2010a and 2010b; Mostafa and Natarajan, 2009; Shandra, 2007a, 2007b, Shandra, Leckband, McKinney and London, 2009). Graph 1 depicts the trade-off between ecological footprint and happy life years; the (standardized) residuals in our graph are a reformulated Happy Planet Index:

Graph 1: The non-linear relationship between Happy Life Years (HLYE, vertical Y) and ecological footprint (horizontal X), n=140 countries in 2005.

¹¹ <http://www.happyplanetindex.org/>

¹² The most often encountered formulation in the literature is a double logarithmic expression, based on the natural logarithm of development level/energy consumption and its square.

Variable	Coefficient	Std Error
Ecological Footprint per capita	10.541***	1.313
Ecological Footprint per capita ²	-0.677***	0.147
Constant	19.631***	2.246
N =	140	
Adj. R ² =	54.1%	
F-test =	83.081	
p-value =	0.000	

Significance level: * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$;

In a similar vein, we investigated the non-linear trade-offs between ecological footprint and the combined UNDP type indices for six dimensions of development (see Table 2), derived from freely available current cross-national, comparative data:

Table 2: the combined six components, measuring development, and the overall indicators, combining 26 variables

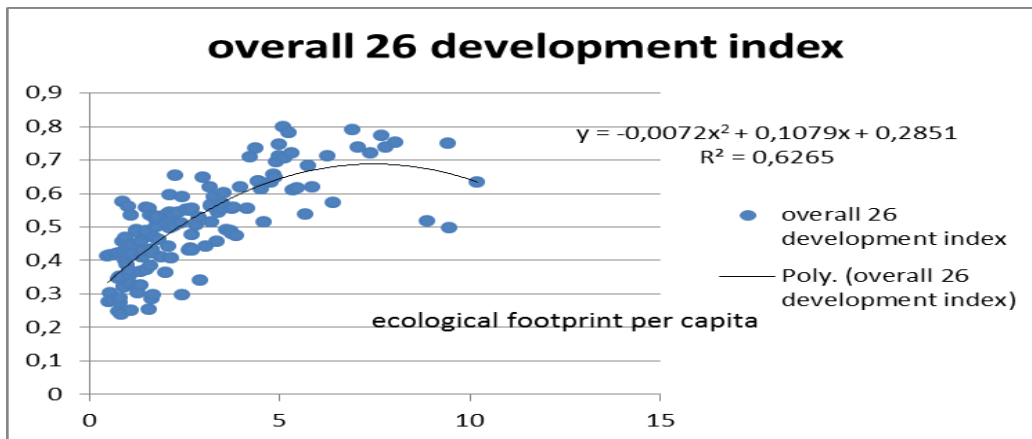

democracy	Combined Failed States Index
democracy	Civil and Political Liberties violations
democracy	Corruption avoidance measure
democracy	Democracy measure
democracy	Global tolerance index
democracy	Rule of law
economic growth	Crisis Performance Factor
economic growth	economic growth IMF prediction growth rate in 2009
economic growth	economic growth IMF prediction growth rate in 2010
economic growth	economic growth in real terms pc. per annum, 1990-2005
Gender equality	closing economic gender gap
Gender equality	closing educational gender gap
Gender equality	closing health and survival gender gap
Gender equality	closing of global gender gap overall score 2009
Gender equality	closing political gender gap
Gender equality	gender empowerment index value
human development	Infant mortality 2005
human development	female survival probability of surviving to age 65 female
human development	Human development index (HDI) value 2004
human development	Life Expectancy (years)
human development	Life Satisfaction (0-10)
R&D	Country share in top world 500 Universities
R&D	per capita world class universities
R&D	tertiary enrollment
social cohesion	quintile share income difference between richest and poorest 20%
social cohesion	unemployment rate
nonparametric_26 equal	overall 26 development index

weights	
nonparametric, weighting each dimension equally	overall 26 development index, based on six dimensions

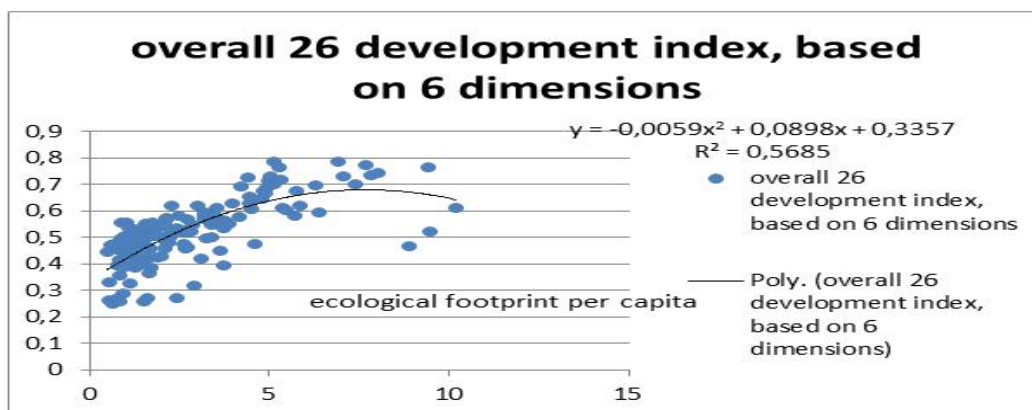

Graphs 2a–2h show the trade-off between ecological footprint and ‘smart development’, measured for the various dimensions (democracy, economic growth, gender equality, human development, research and development, social cohesion, and the two differently combined overall measurement scales). Only the scatterplot for ecological footprint and ‘social cohesion’ suggests a weaker relationship, all the other relationships are considerable. The overall development performance, democracy, gender equality, human development, research and development are a clear non-linear, inverted U-shaped function of ecological footprint per capita, while economic growth and also social cohesion first decrease and then increase with rising levels of ecological footprint per capita.

Graph 2: Ecological footprint and general development performance – the non-linear tradeoffs

Graph 2a: Ecological footprint and the general development performance index, based on an equal weighting of its 26 components

Graph 2b: Ecological footprint and the general development performance index, based on an equal weighting of the six dimensions, underlying the 26 components

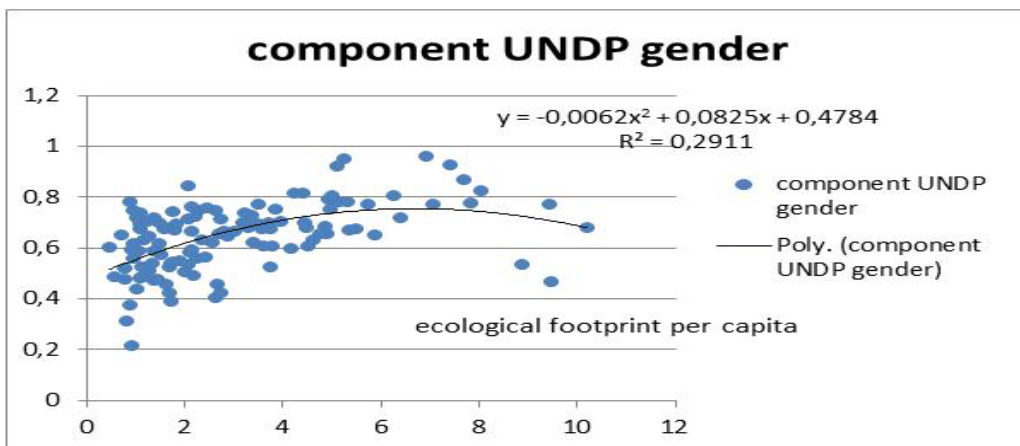

Graph 2c: Ecological footprint and democratic performance (6 components combined)

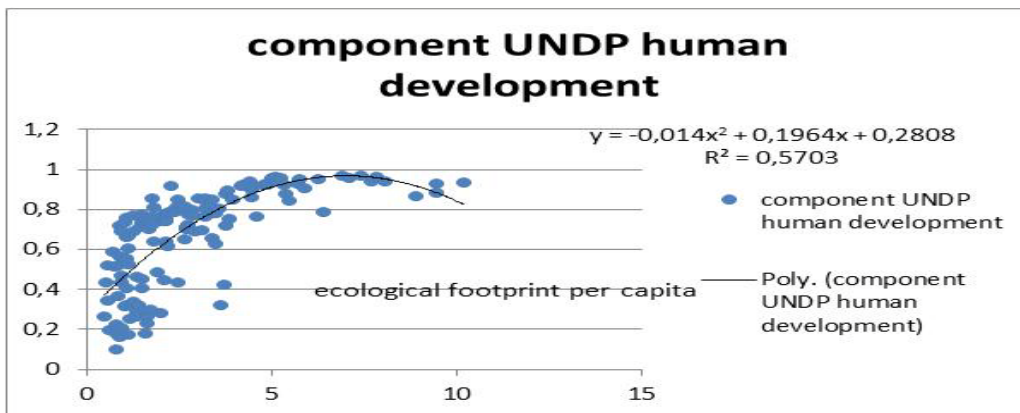

Graph 2d: Ecological footprint and economic growth performance (4 components combined)

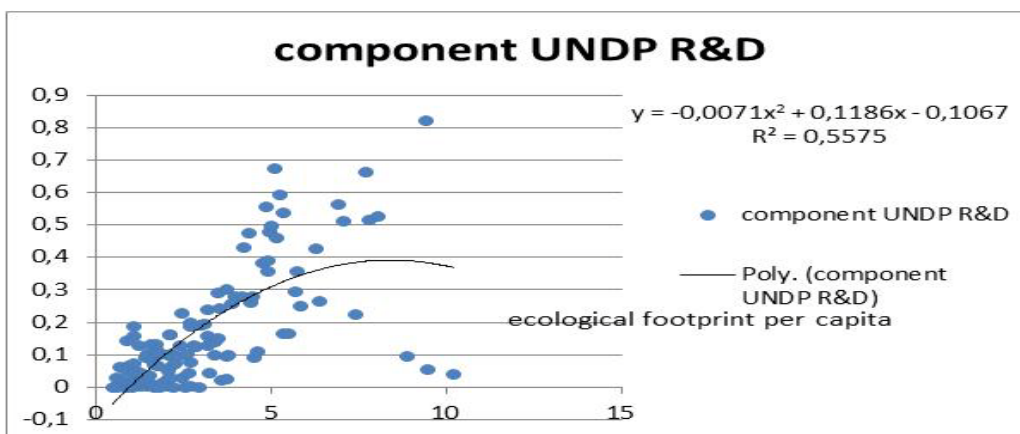

Graph 2e: Ecological footprint and gender equality performance (6 components combined)

Graph 2f: Ecological footprint and human development performance (5 components combined)

Graph 2g: Ecological footprint and research and development performance (3 components combined)

Graph 2h: Ecological footprint and social cohesion performance (2 components combined)

As we already explained, the hitherto existing calculations of the HPI¹³, provided by the Happy Planet Organization, are merely based on simple arithmetical principles.

Following Heintz, 1972 we propose as an alternative method a residual method, and calculate our smart development indicators as the standardized residuals from Graph 2. The standardized residual values are computed as observed minus predicted development outcomes divided by the square root of the residual mean square (see Appendix, Table 1 and 2):

$$(2) \quad SDP_i = (HLYE_i - HLY\hat{E}_i) / \hat{\sigma}$$

High positive outliers imply a very high smart development performance, while countries below the trend line are the countries with a low smart development performance. Having established a residual-based smart Development Indicator family, we now can look more realistically at the cross-national determinants of smart development performance.

4. Results on the drivers and bottlenecks of ‘smart development’

The image of social realities suggested upon a very first inspection of smart development performance values around the globe would suggest a Friedrich August Hayek vision (Hayek, 1945, 1989) of markets, inequality and a free society interacting with one another. There should be no blocks against inequalities in the name of whatever ‘social justice’, explaining then the phenomenal success of the unequal Latin American societies on the parameters of smart development (see especially, the global rankings of smart development in Table 3 of the Appendix). At the same time, the high-equality performers in global society (quintile share of less than 5.0) with a relatively high per-capita income are at the same time bad performers on the new smart development scales. Notably enough, several of these countries are members of the European Union and traditional developed western welfare states. This very first glance at the data would suggest a complete turn-around from the ‘European social model’ (Tausch and Ghymers, 2006) in favor of a high-inequality, open to globalization ‘Latin American model’ or Philippine model as the best way to achieve a good ‘smart development’ performance. However, such a first glance completely overlooks the massive available evidence about world economic openness and the failure of ‘smart development’.

As to multivariate analysis, first preliminary stepwise regression procedures with mean substitution of missing variables revealed a re-current pattern of the importance and predictive capability robustness of the chosen variables among the 26 independent variables with a theoretically well-plausible greater and significant effect on the dependent variables (the six component indicators of development and the overall development performance indicators). The final results were achieved by forward multiple regression based on list wise deletion of missing values, and based exclusively on the significant predictors from the prior preliminary stepwise regressions. We first

¹³ Although we presume the main contemporary global environment indicators to be known, we refer our readers especially to the very comprehensive Yale/Columbia environmental data series, available at <http://sedac.ciesin.columbia.edu/es/esi/> and <http://epi.yale.edu/Home>. The new ‘grammar’ of the global footprint discourse can be found at <http://www.footprintnetwork.org/en/index.php/GFN/page/glossary/>.

present, variable by variable, and driver by driver, and bottleneck by bottleneck, the significant results of our multiple regression analyses (regression coefficients and their significance):

Table 3: The significant drivers and bottlenecks of smart development

Independent Variable	dependent variable	Beta	error probability
% women in government, all levels (feminist theory, stressing the need to feminize structures of government)	overall smart development index, based on 26 variables, weighted equally	0.185	0.045
% women in government, all levels (feminist theory, stressing the need to feminize structures of government)	Smart democracy	0.196	0.007
% women in government, all levels (feminist theory, stressing the need to feminize structures of government)	Smart gender justice	0.300	0.001
% world population (Amin's five monopolies of power)	Smart human development	0.152	0.061
% world population (Amin's five monopolies of power)	Happy Life Years	0.161	0.060

effects of worker remittances on migration sending countries)			
worker remittance inflows as % of GDP (conventional center-periphery models about the negative consequences of the brain drain versus ‘new migration theories’, underlining the positive effects of worker remittances on migration sending countries)	overall smart development index, based on 26 variables, weighting equally the six component dimensions	0.177	0.064
worker remittance inflows as % of GDP (conventional center-periphery models about the negative consequences of the brain drain versus ‘new migration theories’, underlining the positive effects of worker remittances on migration sending countries)	overall smart development index, based on 26 variables, weighted equally	0.208	0.016
worker remittance inflows as % of GDP (conventional center-periphery models about the negative consequences of the brain drain versus ‘new migration theories’, underlining the positive effects of worker remittances on migration sending countries)	Smart R&D	0.229	0.017
worker remittance inflows as % of GDP (conventional center-periphery models about the negative consequences of the brain drain versus ‘new migration theories’, underlining the positive effects of worker remittances on migration sending countries)	Smart gender justice	0.241	0.007
worker remittance inflows as % of GDP (conventional center-periphery models about the negative consequences of the brain drain versus ‘new migration theories’, underlining the positive effects of worker remittances on migration sending countries)	Happy Life Years	0.288	0.002
worker remittance inflows as % of GDP (conventional center-periphery models about the negative consequences of the brain drain versus ‘new migration theories’, underlining the positive effects of worker remittances on migration sending countries)	Smart human development	0.352	0.000
Years of membership in the EU, 2010 (Amin’s theory about the importance of European integration as a counterweight to US dominance in the world system)	Smart democracy	0.183	0.006

The following independent variables wield only ‘good’ and **positive effects** on smart development:

- % women in government, all levels (feminist theory; three effects positive; zero effects negative)
- % world population (Amin’s five monopolies of power; three effects positive; zero effects negative)
- Economic Freedom Score (Amin’s critique of rent-seeking; three effects positive; zero effects negative)
- MNC outward investments (stock) per GDP (Bornschiefer’s dependency theory; one effect positive; zero effects negative)

- population density (José Carlos Mariategui's dependency theory; one effect positive; zero effects negative)
- UNDP education index (Steindl/Kalecki-paradigm; two effects positive; zero effects negative)
- Years of membership in the EU (Amin's theory about the role of integration; one effect positive; zero effects negative)

The following predictors wielded only **negative consequences** on smart development:

- Absolute latitude (Andre Gunder Frank's '*Re-Orient*' model; zero effects positive; one effect negative)
- Annual population growth rate (%) (Paul Israel Singer's dependency theory; zero effects positive; two effects negative)
- Immigration share of total population (%) (Amin's theory about the role of migration; zero effects positive; one effect negative)
- military expenditures per GDP (dependency and peace research approaches; zero effects positive; four effects negative)
- military personnel rate (dependency and peace research approaches; zero effects positive; one effect negative)
- Openness-Index (export-share per GDP minus import-share per GDP) (Amin's conception of the role of the peripheries; zero effects positive, three effects negative)

The following variables wielded mixed results:

- worker remittance inflows as % of GDP (six effects positive; one effect negative)
- Muslim population shares (one effect positive; one effect negative)
- public education expenditure per GNP (one effect positive; two effects negative)

The power, wielded by the predictors

- workers remittances (six positive effects);
- feminization of power structure (three positive effects)
- share of world population (three positive effects)
- economic freedom (three positive effects)
- world economic openness index (three negative effects),
- military expenditures (four negative effects);

seems to be overwhelming.

In the following, we will present, equation by equation, the results of our research. Table 4 shows the significant drivers and bottlenecks of Happy Planet performance, i.e. happy life years in relationship to the ecological footprint of a society used. The z-standardized residuals from Graph 2 are well-explained; our equation is based on 103 countries with complete data. Our equation explains 29% of total variance, the F-value for the entire equation is 9.339, and the error probability is 0.000. The constant is -124.628 and is significant. There is a clear 'Kuznets' curve at work (see also Stern, 2004). But the shape of the curve contradicts much of the earlier debate on the subject: with rising per capita incomes, problem solving capacities first increase and then

decrease. The larger states in the world system, having a larger share of global population, are much better able to achieve a good happy life years performance at relatively low ecological costs, measured in ecological footprints than smaller nations. This clearly contradicts the ‘small is beautiful’ philosophy in the tradition of Kohr and Schumacher. Military expenditures are a clear additional burden on an ecologically viable happy planet performance, while societies, depending on worker remittances, clearly manage to perform better on this scale than other societies around the globe.

Table 4: The drivers and bottlenecks of Happy Planet performance

Independent Variable	B	standard error	Beta	t-value	error probability
Constant	-124.628	42.647		-2.922	0.004
% world population	0.596	0.313	0.161	1.904	0.060
ln GDP per capita	26.062	10.069	3.136	2.588	0.011
ln GDP per capita ^2	-1.309	0.584	-2.731	-2.241	0.027
military expenditures per GDP	-1.098	0.376	-0.245	-2.922	0.004
worker remittance inflows as % of GDP	0.420	0.133	0.288	3.153	0.002
<i>memorandum item: statistical properties of the equation</i>	adj R ²	df	F	error probability of the entire equation	
	29.000	102	9.339	0.000	

In a similar fashion, we can establish in Table 5 that in the 101 countries with complete data, smart overall development, as defined in Graph 2a of this work, is explained to 37% by our model. The F-test for the entire equation is 9.392, the error probability is 0.000. The constant is -2.486 and is significant. The ten countries of the world system, best combining the performance on our 26 development indicators and avoiding ecological footprint at the same time are the Philippines; Sri Lanka; Costa Rica; Sweden; Jamaica; Dominican Republic; Finland; Peru; Netherlands; and Trinidad and Tobago. The ten worst performers on this scale are Sudan; Bosnia and Herzegovina; Central African Republic; United Arab Emirates; Niger; Kuwait; Chad; Zimbabwe; Burundi; and Hong Kong, China (SAR). Feminism in power, economic freedom, population density, the UNDP education index as well as the receipt of worker remittances all significantly contribute towards a smart overall development, while high military expenditures and a high world economic openness are a bottleneck for ‘smart overall development’.

Table 5: Drivers and bottlenecks of smart overall development

Independent Variable	B	standard error	Beta	t-value	error probability
Constant	-2.486	0.533		-4.666	0.000
% women in government. all levels	0.025	0.012	0.185	2.027	0.045
2000 Economic Freedom Score	0.031	0.010	0.336	3.239	0.002
military expenditures per GDP	-0.076	0.032	-0.191	-2.345	0.021
Openness-Index. 1990 (export-share per GDP + import-share per GDP)	-0.004	0.002	-0.170	-2.007	0.048

population density	0.002	0.001	0.214	2.612	0.010
UNDP education index	0.945	0.445	0.198	2.123	0.036
worker remittance inflows as % of GDP	0.027	0.011	0.208	2.459	0.016
<i>memorandum item: statistical properties of the equation</i>	adj R ²	df	F	error probability of the entire equation	
	37.000	100	9.392	0.000	

Also, it emerges that the results about the drivers of overall **smart development performance** are similar to the ones, reported in Table 6, if we calculate the overall development performance by weighting equally its six component indices and only then calculating the overall final country performance score, and not, unlike in Table 5, being the sum of the equally weighted 26 original component indices (as to the trade-off with ecological footprint, see Graph 2b of this work). Economic freedom, and received worker remittances per GDP again emerge as the 'drivers' of smart development (Table 6), while the bottlenecks of smart overall development performance are again military expenditures per GDP and world economic openness. This time, the adjusted R² is 19%, and the equation is based on 102 countries with complete data. The F-test for the entire equation is 6.908, and the equation is significant at the 0.000-level. The constant is -1.469 and is significant.

Table 6: Drivers and bottlenecks of smart overall development, based on an index, which weights the six dimensions equally

Independent Variable	B	standard error	Beta	t-value	error probability
Constant	-1.469	0.536		-2.741	0.007
2000 Economic Freedom Score	0.035	0.008	0.402	4.158	0.000
military expenditures per GDP	-0.061	0.034	-0.166	-1.808	0.074
Openness-Index. 1990 (export-share per GDP + import-share per GDP)	-0.005	0.002	-0.222	-2.376	0.019

<i>memorandum item: statistical properties of the equation</i>	adj R ²	df	F	error probability of the entire equation	
	19.000	101	6.908	0.000	

Table 7 is an invitation to consider the drivers and bottlenecks of '**smart democracy**' (see also Graph 2c of this work). The ten smartest democracies of our globe are Costa Rica; Netherlands; Jamaica; Chile; Sweden; India; Benin; Madagascar; Finland; and Germany; these are the countries of the world system, best combining democratic performance and avoiding ecological footprint. The worst performers are Sudan; Belarus; Kazakhstan; Kuwait; United Arab Emirates; Uzbekistan; Lebanon; Hong Kong, China (SAR); Azerbaijan; and Myanmar. The adjusted R² of our equation is 48.6%, and the F-value for the entire equation is 25.743, and the error p for the equation is .000. It is based on 132 countries with complete data. The drivers of smart democracy are feminized structures of government, economic freedom, and years of membership in the European Union. The significant bottlenecks of smart democracy

are high military personnel ratios, and a high share of immigrant population. The constant of our equation is -2.037, and it is significant.

Table 7: Drivers and bottlenecks of smart democracy

Our next Table, Table 8, analyses the drivers and bottlenecks of ‘**smart economic growth**’ (combining high economic growth with low rates of ecological footprint per capita (see also Graph 2d of this work)). The IMF data for economic growth in 2010 as well as the Happy Planet Organization data on ecological footprint suggest that the 10 best performers were China; Azerbaijan; Botswana; Uzbekistan; Congo (Democratic Republic of the); Bhutan; Sudan; Mongolia; Ethiopia; and Lebanon; while the worst performers with the worst ‘cocktail’ of slow economic growth in relation to their ecological footprint per capita were Zimbabwe; Moldova; Lithuania; Latvia; Ukraine; Jamaica; Haiti; Armenia; Tajikistan; and Madagascar. Our equation about ‘smart growth’ is based on 111 countries with complete data, the R² is 25.2%, the F-value is 10.243, and the error probability of the entire equation is 0.000. The constant is 0.195, and it is not significant. Population size in relation to the global population as well as Muslim population share per total population are the significant drivers of smart development in the global system today, while absolute latitude (i.e. countries in the far North and South of the world system) as well as nations depending on worker remittances are the bottlenecks of ‘smart growth’ today. This again suggests, as we already hinted at in our theoretical introduction above about the theory of Andre Gunder Frank, 1999, the tectonic shifts in the geographical structures of global growth today, away from the countries of the ‘North Atlantic arena’ towards the nations of the Indian Ocean and the Pacific, which also thwart the smart growth efforts of the countries exporting their workforce to the hitherto existing centers of the global economy.

Table 8: Drivers and bottlenecks of smart economic growth (2010)

Table 9 of our study analyses the drivers and bottlenecks of **smart gender justice**. We are comparing the given amount of gender equality in a society with the amount of resources (ecological footprint), needed to sustain it (see Graph 2e). The global best performers on this equation, how to achieve a maximum of gender justice with a minimum of ecological footprint, are the Philippines; South Africa; Finland; Norway; Mozambique; Sweden; Iceland; Kyrgyzstan; Sri Lanka; and Uganda. The worst balance sheet on this item of combing ‘lilac’ gender policies and ‘green’ issues (minimizing ecological footprint per capita) are Yemen; Saudi Arabia; United Arab Emirates; Turkey; Pakistan; Chad; Iran; Kuwait; Korea (Republic of); and Egypt. Our equation, based on the 93 countries with complete data, explains 39% of total variance, achieves an F-value of 15.712 and an error probability of the entire equation of 0.000. The insignificant constant has the value of -0.034. Women in government and worker remittances per GDP are the significant drivers of smart gender justice, while high military expenditures and the Muslim population share per total population are the major variables, to be interpreted as ‘bottlenecks’ of smart gender justice.

Table 9: Drivers and bottlenecks of smart gender justice

Independent Variable	B	standard error	Beta	t-value	error probability
Constant	-0.034	0.213		-0.161	0.873

Table 10 looks at the drivers and bottlenecks of ‘**smart human development**’. Which are the countries best combining the task of a maximum of ‘human development’ with a minimum of ecological footprint per capita (see also Graph 2f of this work)? The ten best practice countries on this scale are Jamaica; Philippines; Cuba; Sri Lanka; Costa Rica; Vietnam; Dominican Republic; Indonesia; Colombia; and Moldova; while all the worst performers are located in the African continent, comprising the following countries: Botswana; Namibia; Central African Rep.; Burkina Faso; Niger; Sierra Leone; Zimbabwe; Mali; Angola; and Chad. Our equation explains 29.9% of the total variance of ‘smart development’ and is based on the analysis of the 115 countries with

complete data; the F-value is 13.183 and the error p of the entire equation is 0.000. The constant, which is weakly significant, has a value of -1.657. The drivers of ‘smart human development’ are the share of a country’s population in world population, indicating the relative size of a nation, the UNDP education index, measuring the levels of education in a given country, and worker remittance inflows as % of GDP. The bottleneck of ‘smart human development’ is constituted by the crowding-out effect of public education expenditures on human development.

Table 10: Drivers and bottlenecks of smart human development

Table 11 analyses the drivers and bottlenecks of **smart R&D performance**. The equation is based on 93 countries with complete data, the R² is 33%, the F-value is 10.058, and the error probability of the entire equation is 0.000. The constant, which is not significant, is 0.326. The drivers of smart R&D performance, combining the R&D record with a minimum of ecological footprint (see also Graph 2g of this work), are the dominant position of a country on the global markets, expressed in the indicator multinational corporation outward investments per GDP, the public education expenditure, and worker remittance inflows as a % of GDP. The significant bottlenecks against a smart R&D performance are population pressure (the annual population growth rate) and world economic openness. According to our indicator, the best performing countries are the United States (because of its overwhelming performance in tertiary education and research, its high ecological footprint notwithstanding); Sweden; New Zealand; Finland; Israel; United Kingdom; Netherlands; Norway; Switzerland; and Kyrgyzstan. The worst performers are: United Arab Emirates; Luxembourg; Kuwait; Namibia; Botswana; Cyprus; Bosnia and Herzegovina; Macedonia; Uruguay; and the Czech Republic.

Our last result is presented in Table 12. It features on the preconditions of ‘**smart social cohesion**’, combining a relatively high social cohesion with a relatively low ecological footprint (see also Graph 2h). Our equation is based on an analysis of 120 countries with complete data, the adjusted R² is just 8.7%, and the F-value is 6.771; and the error probability of the entire equation is .002. The constant is 0.824 and is significant. There are two significant bottlenecks and no positive drivers of smart social cohesion – annual population growth (population pressure) and the crowding-out effects of public education expenditures per GDP. The best results on our indicator are achieved by several less developed and or (former) communist or left wing regime countries as well as nations with a known record of relatively egalitarian development policies (South Korea), with the entire group comprising: Chad; Uzbekistan; Rwanda; Belarus; Laos; Cuba; Benin; Tajikistan; Korea (Republic of); and Thailand. The worst record of combining social cohesion with low ecological footprints was found in Djibouti; Namibia; Bosnia and Herzegovina; Central African Republic; Sierra Leone; Botswana; Macedonia; Bolivia; South Africa; and Colombia.

5. Discussion

Knight and Rosa, 2011 compared the ecological footprint per capita and average life satisfaction (as a measure of subjective well-being). Based on maximum likelihood estimations, they tested the effects of climate, political, economic, and social factors on environmental efficiency of well-being (EEWB) with a sample of 105 countries. Knight and Rosa found a negative quadratic effect of economic development on

EEWB, a negative effect of income inequality, and a positive effect of social capital (based on social trust data, contained in the *World Values Survey*)¹⁴.

Our residuals-based reformulation of smart development realistically captures the trade-off between Global Ecological Footprint per capita and development performance and offers to us a better idea about smart development performance at different stages of socio-economic development. Our results show that traditional indicators of economic globalization and also inequality have little influence on smart development performance, but that hitherto neglected elements of dependency and world systems theory gain in importance. This is especially relevant for the socio-economic theory of Samir Amin, but it is also true of the contributions by feminism, peace research, and by other various approaches in the globalization critical tradition, perhaps hitherto neglected here and there. Efficiency tends to increase and then to decrease with rising development levels. Big countries with large population resources perform better on our scales, and military expenditures/personnel rates are a significant block against smart development performance. In a sense, our results also contradict the logic inherent in the 'beautiful', but unfortunately wrong '*small is beautiful*' analysis, proposed by Schumacher, 1973a: not the small countries, but the big countries find it easier to have a satisfactory smart development performance in comparison to the ecological footprint, consumed by them. Our research also shows the beneficial effects of migration on the sending countries. Worker remittances have a significant positive effect on the HPI and a host of other smart development indicators. Migration sending countries, as to be expected from Samir Amin's dependency theory, reap substantial benefits from receiving worker remittances, while other indicators of globalization hardly affect the smart development performance.

Only the following significant effects highlight the necessity to further develop the paradigm, developed here: the negative, crowding out effects public education expenditures per GDP on smart social cohesion and smart human development, and the negative effects, worker remittance inflows as % of GDP wield on smart economic growth. The impressive list of tests, speaking in favor of the globalization critical paradigm, presented in this work, would suggest to further developing this research approach to questions of 'smart development'.

First of all, the dependency and world systems paradigm by Samir Amin comes to our mind. As correctly predicted by Samir Amin, the big countries with huge population resources today are favored in their smart economic growth, their Happy Life Years, and their smart human development. As correctly expected by Amin, peripheral rent seeking is a burden and its absence, measured by economic freedom, is an asset among the forces, shaping international development today, especially for smart democracy, and the overall smart development index (both formulations, used in this essay). In addition, Amin correctly stresses the necessity for European integration – and the positive effects of years of EU membership on smart democracy confirm Euro-optimism. He correctly analyses the enormous transfer of resources from the center to the periphery, brought about by migration, with the huge statistical observed effects of received worker remittances on smart human development, Happy Life Years, smart gender justice, smart R&D, and both formulations of the smart development index justifying his assumption. Amin's dependency theory correctly predicts the very

¹⁴ <http://www.worldvaluessurvey.org/>

negative effects of world economic openness on smart development. The huge statistical negative and very uniform effects, to be observed, cannot be simply and easily rejected out of hand: smart R&D and overall smart development (both formulations) are affected negatively by world economic openness. Among the major four founding figures of the 'world systems approach' (Amin, Arrighi, Frank and Wallerstein, 1982) he is the only one to have come up, in addition, with a consistent and far-reaching critique of Islamism, confirmed by the very negative trade-off between Muslim population share and smart gender empowerment.

But in some ways, Amin's paradigm has to be expanded and refined: Feminism is an important driver of smart gender justice, smart democracy, and the overall smart development index, based on 26 variables, weighted equally. Feminist approaches, in principle, would be well compatible with Amin's original approach. The Kalecki/Steindl paradigm also can be merged with Amin's theory, and it has three significant results to its favor – the positive determination of smart R&D by public education expenditures, and the positive effects of the UNDP education index on smart human development and on overall smart development index, based on 26 variables, weighted equally. Several further strains of dependency/world systems research are confirmed in this essay: Bornschier's dependency theory and the importance it attaches to multinational corporation headquarter status, which is confirmed by the positive effect of this variable on smart R&D; and the effect of population density, predicted in José Carlos Mariategui's dependency theory on the overall smart development index, based on 26 variables, weighted equally. Paul Israel Singer's approach to dependency and population dynamics is confirmed by the significant negative effects of annual population growth rates on smart R&D and smart social cohesion. The following empirical results could be interpreted to be expressions of Andre Gunder Frank's Re-Orient hypothesis, 1999 about a fundamental shift in the global production dynamics away from the old centers towards the countries of the Indian and the Pacific Ocean: the significant positive effect of Muslim population share per total population on smart economic growth, and the significant negative effects of absolute latitude on smart economic growth, of immigration - share of population in 2005 on smart democracy (the biggest migration recipients are the countries of the global 'North'), and worker remittance inflows as % of GDP on smart economic growth.

For some other processes, the empirical Amin's five monopolies of power include two elements of military might, the monopoly of technology, supported by military expenditures of the dominant nations, and the monopoly of the military means of mass destruction. But the significant negative effects of military expenditures (on Happy Life Years, smart gender justice, the two formulations of the overall smart development index) or military personnel rates (smart democracy) on smart development rather support the arguments of quantitative peace research during the last decades with its apprehensions against very high military spending rates (Auvinen and Nafziger, 1999; Heo, 1998; Mintz and Stevenson, 1995).

As we stated, the real differences with the theories presented here are to be found in the negative effects of public education expenditures per GDP on smart social cohesion and smart human development. In this case, our response can only be to draw the global research community to the essays published by Blankenau and Simpson, 2004 and Sylwester, 2000, written from the perspective of established economic theory. Blankenau and Simpson, 2004, because, as we already stated, they investigated the

public education expenditure-growth relationship in the context of an endogenous growth model in which private and public investment are inputs to human capital accumulation. They could show that the positive direct effect of public education spending on growth can be diminished or even negated when other determinants of growth are negatively affected by general equilibrium adjustments. Blankenau and Simpson showed that the response of growth to public education expenditures may be non-monotonic. The relationship depends on the level of government spending, the tax structure and the parameters of production technologies. Sylwester, 2000, for his part could demonstrate that although public education expenditures are positively associated with future economic growth, the contemporaneous effect upon growth is negative.

6. Conclusions

Since all existing major comparative empirical studies on drivers and bottlenecks of environmental quality only touched upon different dependent variables, and not the smart development, this first international comparative study suggest cautiously that future research efforts in comparative environmental science would be well advised to take the major predictor variables of the present study as well as the environmental plateau curve into account (see also Weede and Kampf, 2002; de Haan, Lundstrom and Sturm, 2006; and Gwartney, Lawson and Holcombe, 1999).

It emerges that the absence of ‘rent seeking’, economic freedom and a free price mechanism, and worker remittances are the most important drivers of ‘smart development’. Most of the ‘small is beautiful’ assumptions of Schumacherian economics by contrast do not stand the test of cross-national development accounting and are squarely contradicted by our empirical results; with population density and population size always being among the drivers, and not the bottlenecks of ‘smart development’.

As correctly predicted by Samir Amin, the big countries with huge population resources today are favored in their smart economic growth, their Happy Life Years, and their smart human development. As correctly expected by Amin, peripheral rent seeking is a burden and its absence, measured by economic freedom, is an asset among the forces, shaping international development today, especially for smart democracy, and the overall smart development index. In addition, Amin correctly stressed the necessity for European integration – and the positive effects of years of EU membership on smart democracy confirm Euro-optimism. He correctly analyzed the enormous transfer of resources from the center to the periphery, brought about by migration, with the huge statistical observed effects of received worker remittances on smart human development, Happy Life Years, smart gender justice, smart R&D, and both formulations of the smart development index justifying his assumption. Amin’s dependency theory correctly predicted the very negative effects of world economic openness on smart development. The huge statistical negative and very uniform effects, to be observed, cannot be simply easily rejected out of hand: smart R&D and overall smart development are affected negatively by world economic openness. Among the major four founding figures of the ‘world systems approach’ (Amin, Arrighi, Frank and Wallerstein, 1982) he is the only one to have come up, in addition, with a consistent and far-reaching critique of Islamism, confirmed by the very negative trade-off between Muslim population share and smart gender empowerment.

We could also show in this article the importance of Feminism, the Kalecki/Steindl paradigm, the multinational corporation headquarter status, population density, population dynamics, Muslim population share per total population, absolute latitude, and migration on 'smart development'. We also investigated the negative effects of public education expenditures per GDP on smart development.

We are aware that our answers, raised to the questions in this article, are incomplete. But we hope to have provided at least some preliminary guiding posts for further research on this important subject.
