Forecasting GDP at the Regional Level with Many Predictors

Abstract

In this paper, we assess the accuracy of macroeconomic forecasts at the regional level using a unique data set at quarterly frequency. We forecast gross domestic product (GDP) for two German states (Free State of Saxony and Baden-Württemberg) and Eastern Germany. We overcome the problem of a 'data-poor environment' at the sub-national level by including more than 300 international, national and regional indicators. We calculate single–indicator, multi–indicator and pooled forecasts. Our results show that we can significantly increase forecast accuracy compared to an autoregressive benchmark model, both for short- and long-term predictions. Furthermore, our best leading indicators describe the specific regional economic structure better than other indicators.

JEL-Code: C320, C520, C530, E370, R110.

Keywords: leading indicators, regional forecasting, forecast evaluation, forecast combination, data rich environment.

October 1, 2012

1. Motivation

Regional policy makers are increasingly interested in reliable forecasts of macroeconomic variables (e.g., gross domestic product) at the regional level. Such forecasts are important to the decision-making process (e.g., for fiscal policy planning). Because regional policy can assume identical business cycles at the regional and national level, decision makers can appraise future regional economic output with national forecasts. However, using national forecasts can lead to mis-estimation because of a high degree of regional heterogeneity (e.g., different economic structures).

A high heterogeneity among regional units is observable for Germany, for example. The 16 German states are characterized by high disparity in their economic structures. This disparity is explicitly reflected in annual growth rates for real gross domestic product (GDP). Figure 1 shows the annual growth rates of real GDP in 2009. Whereas the economic output of

Figure 1: Percentage change of real GDP in 2009 for the German states

Source: Working Group Regional Accounts VGRdL (2011), author's illustration.

a highly industrialized and export-dependent German state such as North Rhine-Westphalia shrinks by 5.6%, the GDP growth rate of Berlin, which is characterized by a large amount of different services, lies at -0.5%. The economic recession of 2009 affected the regional units with different intensities. Obviously, the growth rate of Germany (-4.7%) does not seem to be a good approximation for an increase in GDP for all sub-national German regions.¹

Macroeconomic aggregates beneath national states (e.g., Germany) are difficult to forecast, especially because of data limitations and a low frequency of data publication. For economic forecasts, it is absolutely necessary to know in which phase of the business cycle the whole economy actually is. It is only possible to provide unbiased predictions with such information. With data published at a higher frequency, it is possible to reduce forecast errors and

¹Schirwitz et al. (2009) show that significant differences between regional business cycles in Germany exist.

therefore send more accurate signals to regional policy makers.

The literature includes many studies on (supra-)national aggregates, as for the Euro Area (see e.g., Bodo *et al.* (2000), Forni *et al.* (2003) or Carstensen *et al.* (2011)) and Germany (see e.g., Kholodilin and Siliverstovs (2005), Breitung and Schumacher (2008) or Drechsel and Scheufele (2012b)), but only a few attempts have been made to predict economic output at the regional level.²

Bandholz and Funke (2003) construct a leading indicator for Hamburg, notably to predict turning points of economic output. Dreger and Kholodilin (2007) use regional indicators to forecast the GDP of Berlin. A study by Kholodilin *et al.* (2008) employs dynamic panel techniques to forecast GDP on an annual basis for all German states at the same time, accounting for spatial effects between regional units. In addition, a few studies forecast regional labor market indicators for Germany. First, Longhi and Nijkamp (2007) predict employment figures for all West German regions and specifically address the problem of spatial correlation. Second, Schanne *et al.* (2010) forecast unemployment rates for German labor-market districts, using a GVAR model with spatial interactions. The before mentioned studies employ different data frequencies, whereas Bandholz and Funke (2003) and Dreger and Kholodilin (2007) use annual GDP information disaggregated into quarterly data, and Kholodilin *et al.* (2008) and Longhi and Nijkamp (2007) use only annual data. Schanne *et al.* (2010) have instead data on a monthly basis.

Our paper adds to these prominent studies in several ways. First, we overcome the problem of data limitations at the regional level using a unique data set with quarterly national accounts for Eastern Germany, the Free State of Saxony³ and Baden-Württemberg. Altogether, we have 121 regional indicators, including the Ifo business climate for industry and trade in Saxony or new orders in manufacturing for Baden-Württemberg. Second, we use information from regional, national and international indicators and assess their forecasting performance at the regional level. Most of the previously mentioned studies use only a few regional indicators. Finally, our large data set enables the study of the forecasting accuracy of several pooling strategies for regional target variables. We are most likely the first ones who evaluate the properties of a large set of leading indicators and pooling strategies at the regional level.

We combine different strands of the regional-level forecasting literature. We specifically attempt to determine which indicators are important in forecasting regional GDP. Does early information come from international (World or European Union) or national (Germany) leading indicators? Alternatively, does sub-national or regional information increase forecasting performance? Trading partners such as the US or Europe (France, Poland, etc.) as well as the growing importance of Asian economies creates a stronger linkage between

 $^{^{2}}$ In his thesis, Vogt (2009) gives a comprehensive survey of forecast activities for the German states.

³Vogt (2010) studies the properties of a few indicators to forecast regional GDP on a quarterly basis for the Free State of Saxony by combining several outcomes from a VAR-model.

these countries and regional economies. These are two of the several reasons why we include international indicators. Furthermore, shocks that hit the German economy are transmitted through different channels (e.g., the production of intermediate goods) to regional companies. Banerjee et al. (2005) construct a large data set containing leading indicators to forecast Euro-area inflation and GDP growth. In addition, they add comprehensive information from the US economy and find that a set of these variables improves forecasting performance. Banerjee et al. (2006) analyses the importance of Euro-area indicators for the prediction of macroeconomic variables for five new Member States.⁴ Several studies analyze forecasting properties in a data-rich environment for different countries. Schumacher (2010) finds that international indicators do not deliver early information for forecasting German GDP if the data are not preselected. Otherwise, forecasting performance improves with international information. For the small and open economy of New Zealand, Eickmeier and Ng (2011) find that adding international data to nationwide information enhances the quality of economic forecasts. To improve forecasts of Canadian macroeconomic data (e.g., GDP and inflation), Brisson et al. (2003) use indicators from the US as well as other countries. In our study, we use international and German indicators as well as several variables from the sub-national (Eastern Germany) and regional level (Saxony, Baden-Württemberg). To the best of our knowledge, our study is the first to evaluate these questions from a regional perspective.

Furthermore, we add to the existing literature on forecast combinations. The seminal works of Timmermann (2006) and Stock and Watson (2006) show that combining forecast output from different models leads to improved forecast accuracy in comparison to univariate benchmarks or predictions from a single model. Several empirical contributions exist for different single countries (see e.g., Drechsel and Scheufele (2012a) and Drechsel and Scheufele (2012b) for Germany or Clements and Galvão (2009) for the US) or for several states simultaneously (see e.g., Stock and Watson (2004) or Kuzin *et al.* (2012)). Studies at the regional level are absent. Given our large data set, we evaluate the forecast accuracy of different pooling strategies.

The paper is organized as follows: in section 2, we describe our data and empirical setup. Section 3 discusses the results. Section 4 offers a conclusion.

2. Data and Empirical Setup

The following section first presents a short overview of our data. Then, we introduce the general empirical model. Afterwards, different combination approaches are briefly described. Finally, our forecast evaluation strategy is presented.

⁴These new Member States are: Czech Republic, Hungary, Poland, Slovakia and Slovenia.

2.1. Data

The official statistics in Germany do not provide temporal disaggregated macroeconomic data (e.g., quarterly GDP) for regional units. Only annual information is available. Therefore, it is either problematic to find a suitable target variable to forecast or an insufficient number of observations exist. In our paper, we use a new data set which solves these two problems of availability and the length of the time series.

Three different sources exist which provide quarterly national accounts at the German regional or sub-national level. First, Nierhaus (2007) computes quarterly GDP data for the German state Free State of Saxony. He applies the temporal disaggregation method of Chow and Lin (1971), which is used for official statistics of the European Union. The method is based on a stable regression relationship between annual aggregates and indicators with a higher frequency (e.g., monthly). This relationship makes it possible to transform annual data into quarterly data. For this transformation, Nierhaus (2007) uses official German statistics: regional turnovers or quarterly data from national accounts for Germany (e.g., gross value-added). Second, Vullhorst (2008) uses the same temporal disaggregation method as Nierhaus (2007) to calculate quarterly national accounts for the state Baden-Württemberg. Third, the Halle Institute for Economic Research (IWH) provides quarterly data on GDP for Eastern Germany (excluding Berlin).⁵ For all three GDP target variables, data are available for the time period 1996:01 to 2010:04.⁶ The data are provided in real terms, and we make a seasonal adjustment to obtain quarter-on-quarter (qoq) growth rates or interpretable first differences. Figure 2 shows the Chain Index as well as qoq growth rates for Saxon, Baden-Württemberg and Eastern German GDP from 2006:01 to 2010:04.

Figure 2: Real GDP for Saxony, Baden-Württemberg and Eastern Germany

Note: Chain Index 2000 = 100 (left scale), qoq growth rate (right scale, %), seasonally adjusted with Census X-12-ARIMA. SX: Free State of Saxony, BW: Baden-Württemberg, EG: Eastern Germany

Source: Ifo Institute, Statistical Office of Baden-Württemberg and IWH, author's calculation and illustration.

⁵A methodical description can be found in Brautzsch and Ludwig (2002).

⁶The data are updated intermittently and are available from the homepage of the Ifo Institute and the IWH. Data for Baden-Württemberg are available from the regional Statistical Office of Baden-Württemberg.

During that period, the movements of the two curves for the chain indices for Saxony and Eastern Germany are predominantly identical. Only the levels of qoq growth rates differ slightly for different points in time. The movement of the GDP for Baden-Württemberg is similar but much more volatile than the output for Saxony and Eastern Germany. With these three and unique time series, we have suitable target variables at the sub-national or regional level.

Our data set contains **368** leading indicators that can be used for the assessment of forecasting performance for our target variables. All indicators come from different sources and are grouped into seven different categories: macroeconomic variables (94), finance (31), prices (12), wages (4), surveys (74), international (32) and regional (121).⁷ Macroeconomic variables contain industrial production measures, turnovers, new orders and employment figures as well as data on foreign trade and government tax revenues. All of these macroeconomic indicators are measured for the national level here, Germany. The category of financial variables includes data on interest rates, government bond yields, exchange rates and stock indices. Furthermore, we have price data on consumer and producer prices as well as price indices for exports and imports. In addition to these quantitative data, we use qualitative information. Indicators from the category surveys are obtained from consumer and business surveys (Ifo, ZEW, GfK and the European Commission). In addition, composite leading indicators for Germany (e.g., from the OECD) and the Early Bird of the Commerzbank are grouped in this category. International data cover a set of indicators for the European Union and the US from the previously mentioned categories, e.g., the Economic Sentiment Indicator for France and US industrial production. Last, we add different regional indicators for Eastern Germany, the Free State of Saxony and Baden-Württemberg. The regional category covers quantitative (turnovers, prices and data on foreign trade) and qualitative information (Ifo and the business survey of the IWH).

The data set is predominantly the same one used by Drechsel and Scheufele (2012a), and we add regional indicators for Eastern Germany (40 indicators), the Free State of Saxony (42 indicators) and Baden-Württemberg (39 indicators). Most of these leading indicators are available on a monthly basis. Hence, a transformation into quarterly data is necessary. First, we seasonally adjust the monthly indicators.⁸ Second, we calculate a three-month average to obtain quarterly data.

If necessary, we transform our data to obtain stationary time series. Table 4 in the Appendix also contains information about the transformation of the indicators.

⁷For a complete description of our data, see Table 4 in the Appendix.

⁸All variables and indicators are seasonally adjusted with Census X-12-ARIMA.

2.2. Indicator forecasts

To generate multiple step-ahead forecasts, we use the following autoregressive distributed lag (ADL) model

$$y_{t+h}^{k} = \alpha + \sum_{i=1}^{p} \beta_{i} y_{t+1-i} + \sum_{j=1}^{q} \gamma_{j} x_{t+1-j}^{k} + \varepsilon_{t}^{k} , \qquad (1)$$

where y_{t+h}^k stands for the *h*-step-ahead model *k* of the qoq growth rate of Saxon, Baden-Württemberg or Eastern German real GDP and x_t^k denotes the exogenous leading indicator from the regional, national or international level. Because we use quarterly data, a maximum of 4 lags, both for the lagged dependent and independent variables, is allowed. The optimal length for *p* and *q* are determined by the Schwarz Information Criterion (BIC). We apply a recursive forecasting approach with the initial estimation period ranging from 1996:01 to 2002:4 (T = 28). This initial period is enlarged successively by one quarter. In every step, the forecasting model of Equation (1) is newly specified. For each forecast horizon, the first forecast is calculated for 2003:1 and the last for 2010:4. Our forecast horizon *h* has four dimensions: $h \in \{1, 2, 3, 4\}$. Because we implement the ADL model as a direct-step forecast, we always produce N = 32 forecasts for h = 1 (short term) or h = 4 (long term) and every single indicator k. As the benchmark, we choose the standard AR(p) process.

There may be an information gain from applying a multi-indicator forecast model. Hence, combining regional with either national or international indicators may reduce forecast errors due to a combination of different information sets; thus, we modify the model in Equation (1) by adding another indicator

$$y_{t+h}^{k} = \alpha + \sum_{i=1}^{p} \beta_{i} y_{t+1-i} + \sum_{j=1}^{q} \gamma_{j} r_{t+1-j}^{k} + \sum_{l=1}^{q} \gamma_{j} z_{t+1-j}^{k} + \varepsilon_{t}^{k}$$
(2)

and we only estimate models for every regional indicator (r_t^k) in combination with an indicator from the national or international level (z_t^k) . Therefore, we have the following extra specifications: for Eastern Germany $40 \cdot 248 = 9,880$, for the Free State of Saxony $42 \cdot 248 = 10,374$ and for Baden-Württemberg $39 \cdot 248 = 9,633$.

2.3. Combination strategies

Consistent with the literature on forecast combinations, the following section presents the different pooling strategies that we apply. It is well known that an appropriate in-sample fitted model could have a bad out-of-sample performance, thus producing high forecast errors. Stock and Watson (2006) and Timmermann (2006) have shown the advantage of combining forecasting output from different models. This advantage has been confirmed in numerous empirical studies for different countries (see e.g., Drechsel and Maurin (2011) or Eickmeier and Ziegler (2008)). Evidence for the advantage of pooling at the regional level is absent. With our paper, we fill this gap.

A forecast obtained by pooling \hat{y}_{t+h}^{Pool} is based on the individual indicator forecasts \hat{y}_{t+h}^k and a weighting scheme w_{t+h}^k :

$$\hat{y}_{t+h}^{Pool} = \sum_{k=1}^{K} w_{t+h}^{k} \hat{y}_{t+h}^{k} \quad \text{with} \sum_{k=1}^{K} w_{t+h}^{k} = 1.$$
(3)

Because the weights are indexed by time, they are varying with every re-estimation of our ADL model. K represents the number of models we consider for pooling.

A very simple but empirically well-working scheme (see e.g., Timmermann (2006)) is (i) equal weights: $w^k = 1/K$. The weights are not time-varying and depend only on the number of included individual forecasting models K. In addition to a simple mean, we consider (ii) a median approach. This weighting scheme is time-varying and more robust against outliers. In addition to these simple approaches, we can calculate different weights from two categories: in-sample and out-of-sample. We follow the studies by Drechsel and Scheufele (2012a) as well as Drechsel and Scheufele (2012b) and use in-sample and out-of-sample weighting schemes. We use two **in-sample** measures for the calculation of our weights: (iii) BIC and (iv) R^2 . The two schemes differ only slightly. Whereas the model with the lowest BIC gets the highest weight, the weight of a single model increases with higher R^2 . The weights from these two schemes are time-varying and have the following form:

$$w_{t+h}^{k,BIC} = \frac{\exp\left(-0.5 \cdot \Delta_k^{BIC}\right)}{\sum_{k=1}^{K} \exp\left(-0.5 \cdot \Delta_k^{BIC}\right)} \tag{4}$$

$$w_{t+h}^{k,R^2} = \frac{\exp\left(-0.5 \cdot \Delta_k^{R^2}\right)}{\sum_{k=1}^{K} \exp\left(-0.5 \cdot \Delta_k^{R^2}\right)} ,$$
 (5)

with $\Delta_k^{BIC} = BIC_{t+h}^k - BIC_{t+h,min}$ and $\Delta_k^{R^2} = R_{t+h,max}^2 - R_{t+h,k}^2$.

When applying **out-of-sample** weights, it is appropriate to use the forecast errors of different models. First, we apply a (v) trimming approach.⁹ This weighting scheme filters indicators with a bad performance and does not consider the forecasts of those models. Consistent with the literature, we use three different thresholds: 25%, 50% and 75% of all indicators in ranked order. If an indicator's performance lies within the worst (25%, 50% or 75%) performers, the outcome of that specific forecasting model is not considered for pooling. All of the other forecasts are combined with equal weights. Second, discounted mean squared forecast errors as weights (vi) are used to combine several model outcomes. This approach is based on Diebold and Pauly (1987) and is applied e.g., by Costantini and Pappalardo (2010) and Stock and Watson (2004). The weights from this approach have the following form:

$$w_{t+h}^{k} = \frac{\lambda_{t+h,k}^{-1}}{\sum_{k=1}^{K} \lambda_{t+h,k}^{-1}} \,. \tag{6}$$

⁹For the effectiveness of this approach, see e.g., Drechsel and Scheufele (2012b) or Timmermann (2006).

 $\lambda_{t+h,k} = \sum_{n=1}^{N} \delta^{t-h-n} \left(FE_{t+h,n}^{k} \right)^2$ represents the sum of discounted (δ) forecast errors of the single-indicator model k. The literature finds no consensus for how the discount rate δ should be chosen. We use different δ ranging from $\delta \in \{0, 0.1, 0.2, ..., 1\}$ and find similar results. To avoid confusing tables, we only show the forecasting performance for $\delta = 0.1$. In this study, we will only combine forecasts that are calculated from regional indicators (either for Saxony, Baden-Württemberg or Eastern Germany) or the full sample excluding the other two regional units.¹⁰

2.4. Forecast evaluation

To decide whether an single-indicator or two-indicator model as well as different pooling strategies perform better than the chosen benchmark, we first calculate forecast errors from our forecasting exercise. Let \hat{y}_{t+h}^k denote the *h*-step-ahead forecast of model *k*, then the resulting forecast error is: $FE_{t+h}^k = y_{t+h}^k - \hat{y}_{t+h}^k$. The forecast error for the AR-benchmark is FE_{t+h}^{AR} . In a second step, we use the mean squared forecast error (MSFE) as a loss function to assess the overall performance of a single-indicator model. The MSFE for the *h*-step-ahead forecast is defined as:

$$MSFE_{h}^{k} = \frac{1}{N} \sum_{n=1}^{N} \left(FE_{t+h,n}^{k} \right)^{2}.$$
 (7)

The respective MSFE for the autoregressive benchmark is $MSFE_h^{AR}$. Finally, we construct a relative MSFE (rMSFE)

$$rMSFE_h^k = \frac{MSFE_h^k}{MSFE_h^{AR}} , \qquad (8)$$

to decide whether a leading indicator k is performing better or worse in comparison to the AR benchmark model. If this ratio is less than one, the indicator model leads to smaller forecast errors for the respective horizon h. Otherwise, the simple autoregressive model is preferable.

We apply the test developed by Diebold and Mariano (1995) to decide whether a specific $rMSFE_h^k$ is statistically smaller than one. Because the Diebold-Mariano test could suffer from small sample bias, we use a modification of their test proposed by Harvey *et al.* (1997), which corrects for this issue. The idea of this test is straightforward. Under the null hypothesis, the expected forecast errors of two competing models are equal. In other words, the difference in expected forecast errors is equal to zero. Using our notation, the null could be expressed as:

$$H_0: E\left[FE_{t+h}^k - FE_{t+h}^{AR}\right] = E\left[d_{t+h}^k\right] = 0.$$
(9)

¹⁰E.g., for the Free State of Saxony, we use only the indicators for Saxony or all indicators excluding those from Eastern Germany and Baden-Württemberg.

The resulting test statistic of this modified Diebold-Mariano (MDM) test proposed by Harvey *et al.* (1997) is the following:

$$MDM^{k} = \left(\frac{N+1-2h+N^{-1}h(h-1)}{N}\right)^{1/2} \left[\widehat{V}(\overline{d^{k}})\right]^{-1/2} \overline{d^{k}}, \qquad (10)$$

whereas the last product of Equation (10) is the original Diebold-Mariano test statistic, h represents the forecast horizon and $\overline{d^k}$ is the sample mean of the series d_{t+h}^k . An estimation of the variance of the process d_{t+h}^k is denoted by $\widehat{V}(\overline{d^k})$. Following Harvey *et al.* (1997), the critical values for comparison are obtained from a Student's t-distribution with (N-1) degrees of freedom.

3. Results

This section presents the compacted results for our three target variables. First, we discuss the general results of our forecasting exercise. Second, we present detailed and selected results for the leading indicators that are consistent with the specific economic structures of our regional units.

The summary tables are divided into two parts. In the upper part, the top 20 single–indicator models from Equation (1) or pooling strategies for every forecasting horizon are shown. The lower part of the tables presents the results for the estimation with more than one indicator. An improvement in forecasting performance is reached if the two–indicator models from Equation (2) produce lower forecasting errors than the minimum of our single–indicator forecasts or pooling. We only show two–indicator models that fulfill this requirement.¹¹ The minimum for each forecasting horizon is shown in brackets in the lower part of each table. The column Ratio shows the rMSFE from Equation (8). Significant results are indicated with asterisks, presented in the column MDM. To increase readability, we add one column with acronyms for the different sets of indicators. National indicators are denoted with (N), while (I) represents international and (R) regional indicators. Combination strategies are denoted with (C).

3.1. General Results

Tables 1, 2 and 3 present the estimation results for our three regional units.

¹¹To save space, we present the five best models for each forecasting horizon. However, the number of models that produce lower forecast errors than the minimum are shown at the end of every table.

Source: author's calculations.

For all three GDP target variables, we are able to beat the AR(p) benchmark model significantly. This result holds true for all considered forecasting horizons because we find rMSFEin all three tables that are smaller than one. All three tables show that regional, national and international indicators have important information for the prediction of regional GDP. Whereas regional indicators are relevant for the short term (see h = 1 in all three tables), signals for the long term predominantly come from international or national indicators (see h = 4 in Table 1, 2 and 3). Forecasting differences also exist for our regional units. For Saxony, national and regional indicators produce lower forecast errors than the benchmark model. International indicators are relatively negligible for the prediction of Saxon GDP. In contrast, international indicators are more important for Baden-Württemberg and Eastern Germany. The best performance of regional indicators can be found for Baden-Württemberg. Combining regional with national or international indicators improves forecasting accuracy, as the lower parts of Tables 1, 2 and 3 suggest (see the results for the two-indicator models in the lower parts of the tables). We can conclude that the forecasting power of single-indicator models can be increased for all forecasting horizons except in the long term for Eastern Germany. If we want to forecast GDP in Eastern Germany for the next four quarters (h = 4), no model with two indicators beats the minimum of our single-indicator forecast exercise or the outcome of pooling.

Pooling strategies also perform very well at the regional level (see the indicators denoted with (C)). MSFE weights or trimming (25% or 50% as well as for the full sample or only with regional indicators) significantly beat the outcome of the autoregressive benchmark. For Saxony, pooling produces the lowest forecast errors for all horizons. The results for Baden-Württemberg show that pooling is important in the medium term (h = 2). In the long term, several weighting schemes increase forecasting performance for Eastern German GDP.

3.2. Detailed regional results

3.2.1. Free State of Saxony

Surveys (consumer or business) and macroeconomic variables yield the best results for Saxon GDP (see Table 1). The Ifo business expectations and the Ifo business climate for industry and trade in Saxony (IFOBCITSAX, rMSFE = 0.914) produce lower forecasting errors than the benchmark model. These results are consistent with a body of German forecasting literature. One of the most important leading indicators for German GDP is the Ifo business climate for industry and trade.¹² This phenomenon is also the case for Saxony (Lehmann *et al.*, 2010). Furthermore, exports (EXVALUE, rMSFE = 0.922) improve the forcasting accuracy. Within the Eastern German states, the Saxon economy has the highest degree of openness (approximately 40% of all turnovers in the manufacturing sector are gained

 $^{^{12}}$ For a recent survey, see Abberger and Wohlrabe (2006).

from abroad). Another highlight is the importance of national indicators such as domestic turnovers from selling motor vehicles and trailers (TOVEMD) and industrial production of intermediate goods (IPINT). These results are straightforward, because Saxon industry is predominantly described by these two sectors. The top-selling industry in Saxony is vehicle manufacturing. Subcompanies of Volkswagen and BMW are located in Saxony. More than 21% of all turnovers in 2011 are gained in this sector and approximately 39% from the group of intermediate goods producers. Saxon firms are strongly linked to the Western German economy; therefore, national indicators are useful for predicting Saxon GDP.

3.2.2. Baden-Württemberg

In comparison to the Free State of Saxony, the results for Baden-Württemberg are even better. The best indicators predict GDP one quarter ahead almost 50% more accurately then the AR benchmark (see e.g., KIBW in Table 2). Foreign new orders in manufacturing produce lower forecast errors in the short term than the autoregressive model (NOMANB-WTOTF, rMSFE = 0.511). Additionally, turnovers of German capital goods producers (TOCAPD) yield significantly better results than the benchmark. The results from these two separate indicators are consistent with the economic structure of Baden-Württemberg. Baden-Württemberg has the highest share of manufacturing of the German states; approximately 30% of nominal gross value-added is generated in this sector. Manufacturing of motor vehicles (e.g., Daimler AG), machinery and equipment, the fabrication of metal products and highly innovative capital goods producers such as the Bosch Group predominantly describe the industrial structure in manufacturing. In addition to macroeconomic indicators, regional surveys play a major role for predicting GDP in Baden-Württemberg. The Ifo business climate for industry and trade in Baden-Württemberg (IFOBCITBW, rMSFE = 0.664) significantly beats the benchmark model. As mentioned previously, international indicators such as the composite leading indicator for the Euro Area (CLIEUNORM) and the OECD countries (CLITR) perform well. Baden-Württemberg has one of the highest export quotas of the German states; more than 50% of all industrial turnovers are generated in foreign countries. The most important trading partners come from the Euro Area, followed by the US, which also explains the results from our two-indicator models. A combination of regional indicators with, for example, the ISM Purchasing Manager Index for the US reduces forecast errors significantly in comparison to the autoregressive benchmark model (NOMANBWTOTD - USISMP, rMSFE = 0.423). For companies such as Daimler AG and the Bosch Group, the US is one of the most relevant markets.

3.2.3. Eastern Germany

Regional business surveys provided by the Ifo Institute (IFOBSMANEG) and the IWH are able to predict Eastern German GDP better than the autoregressive benchmark in the short

term. An indicator on business expectations in the manufacturing sector and the Ifo business climate for industry and trade in Eastern Germany are very helpful. Considering macroeconomic variables, we also find results that are consistent with the Eastern German economic structure. Domestic turnovers of capital and intermediate goods producers have a higher forecast accuracy than the benchmark (TOINTD, TOCAPD). First, Eastern German firms interact mostly on domestic markets and have a lower export quota in comparison to their Western German counterparts (see Ragnitz (2009)). Therefore, it is not surprising that a combination of the regional business climate for manufacturing and an indicator based on a consumer survey (GFKMPE) produce significantly lower forecast errors than the AR process. Accordingly, the sentiment of consumers sends important signals for Eastern German GDP. Second, the Eastern German industrial sector is mainly characterized by intermediate goods producers. Nearly 40% of all turnovers in 2011 were achieved in this industrial main group. Ragnitz (2009, p. 55) states that most Eastern German firms are still so-called "extended workbenches" (verlängerte Werkbänke) of Western German companies. Overall, Western German economic development is a crucial factor for qoq GDP growth in Eastern Germany. From the short forecasting horizon (h = 1), we can conclude that international indicators also play a role. The composite leading indicator of China decreases forecast errors (CLICNORM). China was the third most important trading partner for Eastern German firms in 2011.

4. Conclusion

This paper analyzes the forecasting performance of leading indicators and pooling techniques at the regional level. We use a large data set with international, national and regional variables. As target variables, we use unique quarterly data for GDP that are provided by different sources for the period 1996:01 to 2010:04. Our paper is the first to systematically use time series techniques to forecast regional GDP.

Altogether, it is possible to predict GDP at the regional level at a quarterly frequency. A large number of indicators produce lower forecast errors than the benchmark model. The different results for our three target variables show that high heterogeneity exists between regional units. An important reason for this heterogeneity is the regional economic structure, as the highlighted section shows. Whereas domestic indicators play a major role in Eastern Germany, international indicators and new orders from foreign countries produce lower forecast errors for GDP in Baden-Württemberg. Furthermore, we can conclude that regional indicators have a high forecasting power, especially in the short and medium term. If it is possible to use regional indicators, a forecaster should not approximate them with national indicators.

As we use a large data set, pooling strategies can improve forecasting accuracy. For all three regional units, trimming or MSFE weights outperforms all other weighting schemes and single–indicator forecasts. Hence, pooling in a regional context is just as important as on the national level.

Finally, we have shown that adding national and international indicators to regional ones leads in most cases to a better forecasting performance than the best single-indicator forecast or pooling technique. Due to data limitations, it is not possible to add more variables. Regional policy makers have to rely on accurate macroeconomic forecasts. With our exercise, we are able to reduce forecast errors significantly and therefore reduce uncertainty about future macroeconomic development at the regional level. This approach renders regional economic policy more assessable.

Further research is necessary for different countries (e.g., the US, EU, etc.) and aggregation levels. It would be interesting to know if it is better to predict regional GDP directly or its different components. This issue was analyzed for Germany as a whole by Drechsel and Scheufele (2012a), but no regional study exists.

Acknowledgements: We are grateful to Marcel Thum, Michael Kloß, Alexander Eck and seminar participants at Dresden University of Technology and Business School of Economics and Law Berlin for their helpful comments and suggestions. We thank Katja Drechsel and Rolf Scheufele for providing their data set on leading indicators.

A. Indicators

Acronym	Indicator	Transformation
Target Variables		
GDPBW	GDP - Baden-Württemberg	1
GDPSAX	GDP - Free State of Saxony	1
GDPEG	GDP - Eastern Germany	1
Macroeconomic V	ariables	
IPTOT	industrial production (IP): total (incl. construction)	1
IPCON	IP construction: total	1
IPENY	IP energy supply: total	1
IPMQU	IP manufacturing: mining and quarrying	1
IPMAN	IP manufacturing: total	1
IPCAP	IP manufacturing: capital goods	1
IPCONDUR	IP manufacturing: consumer durables	1
IPCONNDUR	IP manufacturing: consumer non-durables	1
IPINT	IP manufacturing: intermediate goods	1
IPCONG	IP manufacturing: consumer goods	1
IPCHEM	IP manufacturing: chemicals	1
IPMET	IP manufacturing: basic metals	1
PMECH	IP manufacturing: mechanical engineering	1
IPMOT IPEGS	IP manufacturing: motor vehicles, trailers IP manufacturing: energy, gas etc. supply	1
IPEGS IPVEM	IP manufacturing: energy, gas etc. supply IP manufacturing: motor vehicles, trailers etc.	1
FOCON	turnover (TO): construction	1
TOMQD	TO: mining and quarrying, domestic	1
TOMQF	TO: mining and quarrying, foreign	1
TOMAND	TO: manufacturing total, domestic	1
TOMANF	TO: manufacturing total, foreign	1
TOCAPD	TO: capital goods, domestic	1
TOCAPF	TO: capital goods, foreign	1
TOCONDURD	TO: consumer durables, domestic	1
TOCONDURF	TO: consumer durables, foreign	1
TOCONNDURD	TO: consumer non-durables, domestic	1
TOCONNDURF	TO: consumer non-durables, foreign	1
TOINTD	TO: intermediate goods, domestic	1
TOINTF TOCONGD	TO: intermediate goods, foreign TO: consumer goods, domestic	1
TOCONGE	TO: consumer goods, foreign	1
TOCEOD	TO: computer, electronic and optical products, domestic	1
TOCEOF	TO: computer, electronic and optical products, foreign	1
TOCHEMD	TO: chemicals, domestic	1
TOCHEMF	TO: chemicals, foreign	1
TOMECHD	TO: mechanical engineering, domestic	1
TOMECHF	TO: mechanical engineering, foreign	1
TOVEMD	TO: motor vehicles, trailers etc., domestic	1
TOVEMF	TO: motor vehicles, trailers etc., foreign	1
TOEGSD	TO: energy, gas etc. supply, domestic	1
TOEGSF	TO: energy, gas etc. supply, foreign	1
NOCON	new orders (NO): construction	1
NOMANTOT	NO: manufacturing total	1
NOMANTOTD	NO: manufacturing total, domestic	1
NOMANTOTE	NO: manufacturing total, foreign	1
NOMANCAP NOMANCAPD	NO: capital goods NO: capital goods, domestic	1
NOMANCAPD	NO: capital goods, foreign	1
NOMANCONG	NO: capital goods, loreign NO: consumer goods	1
NOMANCONGD	NO: consumer goods, domestic	1
NOMANCONGF	NO: consumer goods, foreign	1
NOMANINT	NO: intermediate goods	1
NOMANINTD	NO: intermediate goods, domestic	1
NOMANINTF	NO: intermediate goods, foreign	1
NOCHEMD	NO: chemicals, domestic	1
NOCHEMF	NO: chemicals, foreign	1
NOMECHD	NO: mechanical engineering, domestic	1
NOMECHF	NO: mechanical engineering, foreign	1
NOVEMD	NO: motor vehicles, trailers etc., domestic	1
NOVEMF	NO: motor vehicles, trailers etc., foreign	1
NOCEOD	NO: computer, electronic and optical products, domestic	1
NOCEOF	NO: computer, electronic and optical products, foreign	1
CONEMPL	construction: total employment	1
CONTOT CONHOPE	construction: permits issued, total construction: housing permits issued for building	1
CONTROL F	construction. nousing permits issued for building	T

Table 4: Indicators, Acronyms and Transformations

Table 4: Indicators, Acronyms and	I Transformations – continued
-----------------------------------	-------------------------------

Acronym	Indicator	Transformatio
CONNREPE	construction: non-residential permits	1
CONBPGTOT	construction: building permits granted, total	1
CONBPGHO	construction: building permits granted, new homes	1
CONBPGNRE	construction: building permits granted, non-residentials	1
CONHW	construction: hours worked	1
WTEXMV	wholesale trade (WT): total (excl. motor vehicles)	1
WTCLFW	WT: clothing and footwear	1
WTCHEM	WT: chemicals	1
WTCONMA	WT: construction machinery	1
WTSLGF WTEMPL	WT: solid, liquid, gaseous fuels etc. WT: total employment	1
RSEXC	retail sales (RS): total (excl. cars)	1
NRTOT	new registrations (NR): all vehicles	1
NRCARS	NR: cars	1
NRHT	NR: heavy trucks	1
EXVOL	exports: volume index, basis 2005	1
MVOL	imports: volume index, basis 2005	1
UNPTOT	unemployed persons (UNP): total, % of civilian labor	2
EMPLRCTOT	employed persons (EMPL): residence concept, total	1
EMPLWPCTOT	EMPL: work-place concept, total	1
VDAYS	working days: total	1
VACTOT	vacancies: total	1
MANHW	manufacturing: hours worked (excl. construction)	1
TREUCD	tax revenues (TR): EU customs duties	1
RITTOT	TR: income taxes, total	1
TRVAT	TR: value added tax	1
TRVATIM	TR: value added tax on imports	1
TRVATTOT	TR: value added tax, total	1
TRWIT	TR: wage income tax	1
Finance	5	
MMRDTD	money market rate (MMR): day-to-day, monthly average	2
AMRTM	MMR: three-month, monthly average	2
DREUROREPO	discount rate - short term euro repo rate	2
GOVBY	long term government bond yield, 9-10 years	2
/FTBOPB	yields on fully taxed bonds outstanding (YFTBO): public bonds	2
YFTBOCB	YFTBO: corporate bonds	2
YLFBOMS	yields on listed fed. bonds outstand. mat. (YLFBOM): 3-5 years	2
YLFBOML	yields on listed fed. bonds outstand. mat. (YLFBOM): 5-8 years	2
rspi RSD AV	term spread (TS): 10 years, policy inst	0
FSDAY	TS: 10 years, 1Day	0
ISMTH	TS: 10 years, 3Month	0
SPRDAYPR	1Day - policy rates	0
SPRCTB GPC23CPI	corporate - treasury bond	0
DAXSPI	german price competition: 23 industrialized countries, basis: cpi	1
	DAX share price index nominal effective exchange rate	1
NEER	0	1 2
VDAXNVI VDAXOVI	VDAX: new volatility index, price index VDAX: old volatility index, price index	2
		1
M1OD M2MS	M1, overnight deposits M2, money supply	1
M3MS	M2, money supply M3, money supply	1
EMMSM1EP	EM money supply: M1, ep	1
EMMSM1EI EMMSM1F	EM money supply: M1, flows	2
EMMSM1P EMMSM2M1I	EM money supply: M1, nows EM money supply: M2-M1, index	1
EMMSM2M1F	EM money supply: M2-M1, flows	2
MMSM2M11 MMSM3M2EP	EM money supply: M2-M1, nows EM money supply: M3-M2, ep	1
EMMSM3M2E1	EM money supply: M3-M2, ep EM money supply: M3-M2, flows	2
BLDNB	bank lending to domestic non-banks, short term	1
BLDEI	bank fording to demoster hon banks, short term	1
TDDE	time deposits of domestic enterprises	1
SDDE	saving deposits of domestic enterprises	1
	· · ·	
Prices		
CPI	consumer price index	1
PIEE	consumer price index (excl. energy)	1
IWWAPITOT	HWWA index of world market prices: eurozone, total	1
IWWAPIEY	HWWA index of world market prices: eurozone, energy	1
HWWAPIEEY	HWWA index of world market prices: eurozone, excl. energy	1
JIL	oil prices, euro per barrel	1
DILUK	brent oil price, UK average	1
LGP	London gold price, per US \$	1
