Bad Bank(s) and the Recapitalisation of the Banking Sector

With banking sectors worldwide still suffering from the effects of the financial crisis, public discussion of plans to place toxic assets in one or more bad banks has gained steam in recent weeks. The following paper presents a plan how governments can efficiently relieve ailing banks from toxic assets by transferring these assets into a publicly sponsored workout unit, a so-called bad bank. This plan effectively addresses three key challenges. It provides for the transparent removal of toxic assets and gives the banks a fresh start. At the same time, it offers the chance to keep the cost to taxpayers low. In addition, the risk of moral hazard is curtailed.

Public discussion concerning the structural dislocation of the global financial system continues unabated. With the escalation of the financial crisis in the autumn of 2008, many economists advocated internationally coordinated steps to recapitalise the banking sector. The recapitalisation of distressed banks via public funds as well as the creation of bad banks for toxic assets were both proposed early on, yet the international community continues to debate potential solutions.¹ While a general consensus on the principles for the reorganisation of global financial markets was reached at the G20 conference in Washington D.C. on 15 November 2008, the implementation of concrete measures was not addressed until the G20 conference in London on 2 April 2009.

Efforts to master the crisis have fallen short so far. Measures have been implemented primarily at a national level, if they have been implemented at all. As in many other countries, the bank rescue package in Germany has only been partially successful. The package's provisions for the sale of toxic assets have hardly been taken advantage of to date. The debate in Germany concerning the structural reforms necessary as a result of the crisis has drawn renewed attention to existing weaknesses such as the question of whether Germany needs another internationally competitive mega-bank or the still unresolved issue of the economic purpose of the seven federal state banks (Landesbanken). These public banks are partly owned by either one or several German federal states and partly by savings banks. Several Landesbanken have invested large amounts of money into structured products that became toxic in the course of the financial crisis.

Against this backdrop, it seems advisable to maintain a clear separation between the plans for the removal of

toxic assets and the plans to address other structural issues. The creation of bad banks is becoming ever more necessary. The government must confront the problems at hand with a proactive industrial policy so that it can retreat from interventionist measures as quickly as possible. At the same time, the necessary structural adjustments must soon be implemented at private and public banks; German banks must quickly regain their function as sources of credit and as institutes which serve the real economy, in order to counteract the cyclical downturn.

In this paper, we analyse how a bad bank plan can be designed efficiently and evaluate existing proposals, in particular the bad bank plan of the German government. In order to be efficient, a bad bank plan has to address three key challenges. It has to provide for the transparent removal of toxic assets and give the remaining good banks a fresh start. At the same time, the cost to taxpayers has to be kept to a minimum. Finally, the risk of future moral hazard has to be curtailed. The key element of the plan is the valuation of troubled assets at their current market value – assets with no market would thus be valued at zero. The current shareholders will cover the resulting losses. Under the plan, the government would bear responsibility for the management and future resale of toxic assets at its own expense and recapitalise the good bank by taking an equity stake in it. The risk to taxpayers from this investment would be acceptable, however, once the banks are freed of their toxic assets. A

clear emphasis that the government stake is temporary would also be necessary. The government would cover the bad bank's losses, while profits would be distributed to the distressed bank's current shareholders. Either a separate bad bank can be created for each systemically relevant banking institute, or one central bad bank with a separate account for each institute. Under the terms of our proposed plan, bad banks and nationalisation are not alternatives but rather two sides of the same coin. Although we refer mainly to the German situation, the elements of the plan will work in other countries as well.

The rest of the paper is organised as follows. First, we evaluate the situation of German banks in terms of capitalisation, then bad bank solutions of the past are studied and prerequisites for success examined. We then develop a classification scheme for existing and planned bad bank solutions and present an efficient design for a public bad bank. Finally, we evaluate the German Government's bad bank proposal. Two simple numeric examples illustrating the working of both bad bank plans are presented in Boxes 1 and 2.

Weak Capital Basis of German Banks

The capital bases of German banks are seriously endangered by the high quarterly write-down of asset values. A lasting return of confidence cannot be expected without the removal of the troubled securitised assets plaguing the system, which largely have their origin in the US mortgage markets. Figure 1 displays equity capital to assets and core capital ratios (in per cent) for a selection of large banks. Figure 2 displays this data for a selection of German federal state banks (Landesbanken). Some

of these banks have already accepted government assistance in order to stay above the minimum core capital ratio of 4%.²

According to the Bundesbank, the total capital including reserves held by all German banks is approximately 415 billion euros.³ Estimates of the total incurred losses from toxic assets vary at present between 200 and 300 billion euros – in other words, between 8 and 12% of German GDP. The president of the Federal Financial Supervisory Authority (BaFin) recently estimated toxic assets in German banks' balance sheets at 180 to 200 billion euros.⁴ During the Swedish bank crisis in the ear-

² Following the intensification of the financial crisis, many have advocated that a bank's core capital should comprise at least 10% of its risk-adjusted assets. Financial experts view an equity capital to assets relationship of 4 to 5%, and thus a leverage ratio of 25:1 and 20:1, as acceptable for a credit institute. In recent years, leverage ratios of 30:1 for hedge funds have been normal. Nine months before it was shut down by the government in January 1998, the US hedge fund Long Term Capital Management had a leverage ratio of 25:1 (see <https://treas.gov/press/releases/reports/hedgfund.pdf>, p.12).

³ Consolidated balance sheet for German monetary financial institutions (MFIs) from the German central bank's European System of Accounts (cf. <http://www.bundesbank.de/download/statistik/bankenstatistik/S101ATIB01013.PDF>).

⁴ Markus Zydra: Sanio warnt und droht, in: Süddeutsche Zeitung, 20.05.2009.

ly 1990s, write-downs amounted to more than 12% of GDP. Losses of this magnitude – by no means unrealistic in the present crisis – would seriously erode the capital bases of German banks.

The worsening capital position of the banks has a number of consequences with destabilising feedbacks for financial markets and the real economy. Regulatory authorities in Germany are forced to close a bank if its core capital quota falls below 4%. The threat of imminent bank closures is a source of insecurity for market participants and isolates the affected banks from capital flows. In addition, banks are forced to limit the amount of credit they provide if they lack the necessary equity capital. This increases the chances that companies outside the banking sector will have excessive difficulty obtaining credit for their operations. The US savings & loan crisis in the 1980s demonstrated that under the threat of bankruptcy, managers of over-indebted banks are prone to risky behaviour in an attempt to rescue their institutions from failure.⁵ Such risky behaviour is known as “gambling for resurrection”. It is encouraged by the fact that limited liability saves bank managers from incurring potential losses themselves.⁶

The Bad Bank Solution

The creation of one or more bad banks represents a way of overcoming this dilemma.⁷ A bad bank purchases or takes over troubled loans or securities and then attempts to restructure and manage these assets in a way that maximises their value. Once the banks are freed from troubled assets and the need to constantly write down asset values, the negative effects associated with the threat of bankruptcy, a reduction in lending due to a lack of capital, and the readiness to take risks at the expense of creditors and the general public can be minimised or eliminated. However, bad banks do have two drawbacks. First, capital is needed to create a bad bank – potentially in very large amounts. Second, there may be considerable losses at the end of a bad bank’s life. Additional costs will result if the conditions for the purchase of toxic assets represent an incentive for banks to rely on government bailouts in the future. Historical examples show a wide spectrum of different variants of bad banks. The particular plan that is selected deter-

mines the current and future expenses borne by taxpayers when the bad bank is established.

Historical Examples of Bad Banks

The special handling of troubled assets is not uncommon in the day-to-day activities of the banking world. For example, non-performing corporate loans are typically transferred to a work-out department.⁸ In the case of large loan amounts, the individual lenders form creditor pools in order to prevent coordination failures and a sudden withdrawal of lenders that can force a financially distressed firm into bankruptcy.⁹ In the past, work-outs have often resulted in loans being converted into share capital.¹⁰ A bad bank is essentially a work-out department on a much larger scale. When the illiquid assets on the banking industry’s books endanger the entire financial system, a bad bank has often been the solution of choice.

At the end of the 1980s, more than 1,000 savings & loan institutions in the United States were threatened by insolvency due to financing with divergent maturity dates in connection with high interest rates for depositors but comparatively low rates on mortgage lending.¹¹ In 1989, the Resolution Trust Corporation (RTC) – a bad bank – was founded. The RTC was set up with government funding and to a limited extent with money from private investors. Between 1989 and 1995, the RTC took over 747 bankrupt S&Ls with a book value of 394 billion dollars. The S&L bailout cost US taxpayers a total of 124 billion dollars, 76 billion of which fell to the RTC.¹²

In the early 1990s, Sweden attempted to master its banking crisis with several asset management companies. The two most important bad banks – Securum and Retriva – were set up by the Swedish government. Some 3,000 non-performing loans that had been extended to 1,274 troubled companies were transferred from Nordbanken – which had been completely taken over by the government – to Securum. This corresponded to 21% of the bank’s asset portfolio. Retriva, for its part, took over

45% of Gota Bank's assets shortly after the bank was nationalised.¹³

Nordbanken, which took over Gota Bank in 1993, is known today as Nordea Bank, of which the Swedish government still holds a 19.9 % stake.¹⁴ In 2007, the revenues from several sources, dividends, selling of stock and a rising value of the government's remaining equity stake, finally offset the cost of the bailout. That the bailout eventually paid for itself is attributable to the success of Sweden's bad bank plan in minimising losses on troubled assets.¹⁵

In 2001, a Berlin based bank holding company known as the Berliner Bankgesellschaft was threatened with bankruptcy due to the returns it had guaranteed to real-estate fund investors. The city-state of Berlin prevented the closure of the holding company – which also owned Berlin's federal state bank (Landesbank) and savings bank (Sparkasse) – by taking control of it and providing credit guarantees worth over 21.6 billion euros.¹⁶

In 2006, the newly founded Berliner Immobilien Holding (BIH) took over several troubled real-estate funds.¹⁷ The former Berliner Bankgesellschaft was thus effectively separated into a bad bank (BIH) and good bank (Landesbank Berlin). In 2007, the city-state of Berlin managed to sell its 81% stake in the Landesbank Berlin for 4.7 billion euros. BIH has hitherto invested some two billion euros in the re-purchase of shares and the refurbishment and improvement of its properties.¹⁸ Additional investments are planned. The goal is to make its property inventory so attractive that potential buyers will be willing to take over the guarantees provided by Berlin.

Yet in recent years, ailing institutions have also made use of bad banks as a method for repairing the balance

sheets without governmental interference. Between 2003 and 2005, Dresdner Bank transferred 35.5 billion euros in toxic loans and shares which had lost strategic relevance to a so-called Institutional Restructuring Unit (IRU).¹⁹ In 2008, WestLB, the Landesbank partially owned by the state of North Rhine-Westphalia, founded a consolidation vehicle named "Phoenix" in Dublin, Ireland. As an off-balance-sheet special purpose vehicle (without a banking license), Phoenix has already taken over assets with a book value of 23 billion euros. The owners have guaranteed these assets for five billion euros.²⁰ In total, WestLB is planning to hive off assets with a book value of some 80 billion euros.²¹

Prerequisites for the Success of a Bad Bank

Realistically, it must be assumed that a bad bank will produce a loss in the end. If these losses remain low, they can be more readily compensated for by an appreciation in value in other areas – for example, through the increased worth of a government stake in the rescued banks. The government has a good chance of recouping its investment in a bad bank if the following prerequisites are fulfilled:

- troubled assets have been purchased/taken over at a low price;
- active management of these assets is possible;
- financial experts are involved who know how to deal with such assets;
- time is available;
- a clear governance structure has been implemented.

If a market price for an asset does not exist, then the bank being relieved of the asset has an informational edge over the buyer. In this state of affairs, "lemon market" effects are likely. An ailing bank will only transfer assets to a bad bank which have a value below the agreed-upon average price.²² As a result, the bad bank pays inflated prices and generates losses. In this scenario, an excessive burden is also borne by the taxpayer in the recapitalisation of the banking sector.

The restructuring of the acquired assets requires active management. This includes conducting negotiations with debtors, debt rescheduling and, if necessary, debt reductions in order to avoid default. Clearly identifiable

and accessible partners in the negotiation process are thus essential for the effective management of troubled assets.

Another key element in this regard is the creation of attractive investment packages for potential buyers, possibly with government financial support. If the government does not have sufficient access to specialised knowledge for the effective restructuring and management of assets, taxpayers may be forced to cover disproportionately high losses, despite a purchase price that accurately reflects the underlying value of the illiquid assets. Generally, the acquisition of financial experts for the formation of a bad bank is no simple task, as there is a shortage of individuals with the requisite expertise, even at the international level. The pool of individuals with experience in managing troubled assets is small.²³

Fire sales to cover a shortage of liquidity may place downward pressure on asset prices and minimise sale proceeds. If a bad bank lacks sufficient capital to wait for an opportune moment to sell its assets, it will incur unnecessarily high losses. Excessive costs for taxpayers can also be expected if a clear governance structure has not been defined (for decision-making, monitoring and accountability). The executive managers in charge of a bad bank should be able to conduct operations and make decisions regarding the sale or restructuring of assets autonomously, and without being absorbed by issues that only arise because of conflicts of interest between the government and banks.

Methods of Capitalisation and Organisational Structure

The amount of capitalisation required by a bad bank is essentially determined by two factors: operating costs and acquisition costs. When a low price is paid for the acquired troubled assets, this not only minimises the risk of future losses but also keeps the initial capital requirements of the bad bank low.

The source of financing determines whether the government or private sector provides the required start-up funding. The need for liquid funds depends on how the banks being freed of their troubled assets will be “paid.” Liquid funding is not immediately required if a “payment” is made with government securities. However, in this regard the amount of the write-downs and a possible need to re-capitalise the bank are contingent upon whether the book value of the distressed assets exceeds

²³ The shortage of qualified experts is demonstrated by the recurrent involvement of Jan E. Kvarnström, the former director of the Swedish bank Securum. He managed Dresdner Bank’s IRU; according to press reports, worked on behalf of the German government to manage the sale of KfW’s stake in IKB; and helped to manage six billion euros in structured securities held by IKB; cf. H. von Buttlar, N. Luttmer: Der schwedische Bankenlotse, in: Financial Times Deutschland, 24 January 2009.

the book value of the government securities provided in exchange.

If the government provides 100% of the financing – whether in the form of liquid capital or government securities – future losses suffered by the bad bank must be borne first by the taxpayer. The greater the amount paid initially for the troubled assets, the higher the risk of future losses. The participation of the private sector in absorbing these losses can be achieved through negotiation once the bad bank’s final operating result is forthcoming. Alternatively, fixed terms for the distribution of losses can be agreed upon in advance. Such terms cannot foreclose all possibility of future renegotiation, however. In this way, the government is subject to the hold-up problem. This latent threat of potential *ex post* exploitation rises in direct relation to the amount of funding initially provided to establish the bad bank.²⁴

A bad bank plan can be implemented in a centralised or decentralised manner. Under a decentralised plan, each troubled bank is split into its own good and bad bank. Under a centralised plan, all distressed assets in the banking sector are deposited in a single bad bank. If one bad bank were established for each of the three main pillars of the German banking industry – i.e. for the credit unions, savings banks and private banks – this would also qualify as a centralised bad bank plan. Mixed solutions that combine private and public sector funding as well as centralised and decentralised organisational features are also conceivable.

Classification of Historical Precedents and Proposed Models

Table 1 organises known bad bank examples and current proposals according to the source of capitalisation and organisational form. As the Table shows, the majority of known bad banks have been established based on a decentralised organisational model. Retriva and Securum (Sweden) as well as BIH (Berlin) were founded through the subdivision of a bank threatened with insolvency into a good and bad bank. In all three of these cases, the government provided the funding for the bad bank and also recapitalised the good bank in exchange for a shareholder stake.

In each case, the distressed assets were also transferred to the bad bank in a single transaction. This effectively circumvented the need to engage in subsequent negotiations for the distribution of bailout costs. At the same time, a government stake in the good bank is necessary for losses to be recouped and for the possibility

²⁴ The “hold-up problem” is a term that is known from contract theory and from behavioural finance. See O. E. Williamson: Transaction-Cost Economics: The Governance of Contractual Relations, in: Journal of Law and Economics, Vol. 22, No. 2, 1979, pp. 233-62.

BAD BANKS

Table 1
Classification of Bad Banks According to their Capital Source***
and their Mode of Organisation – Historical Examples and Proposals

Created as	Source of Capital		
	Public	Mixed	Private
Centralised bad bank (one bad bank for all ailing banks)	USA – S&L Crisis 1989-1995: RTC	Financial Market Crisis 2007/2008: Public-private Partnership (USA)	
Mixed bad bank (neither centralised nor decentralised)	Financial Market Crisis 2007/2008 Bad bank model of the Association of German Banks: Unique account for each bank	Financial Market Crisis 2007/2008 Multiple, competing public-private Partnership (USA)	
Decentralised bad bank (an ailing bank creates its own bad bank)	Swedish Bank Crisis 1992: Securum, Retriva Berlin – 2001 near insolvency of “Berliner Bankgesellschaft”: BIH Financial Market Crisis 2007/2008: Phoenix (WestLB) Financial Market Crisis 2007/2008: German Government’s proposal		“Mini” Bank Crisis in Germany, 2003/04 in the aftermath of the “new Economy” bust IRU (Dresdner Bank)

Classification of Bad Banks According to the Way of Transfer

Purchase/Takeover of toxic assets	Exchange of toxic assets for secure bonds
Swedish Bad Banks: Securum and Retriva USA: RTC Berlin: BIH	German Government’s proposal: government bonds and covering of losses by shareholders over time Bundesbank proposal: Equalisation claim with debtor warrant Association of German Banks’ proposal: Gov. securities and final accounting with “fair distribution of burdens”

*** Capitalisation is also classified as public if banks receive government bonds instead of money in exchange for toxic assets. Government bonds are simply an alternative way of financing the purchase of toxic assets.

of a net taxpayer gain, or at least to break even, further down the road.

Successful Historical Examples

Sweden’s bad banks, Securum and Retriva, managed to limit losses on non-performing assets. A successful resolution also appears to be on the horizon for Berliner Immobilien Holding.²⁵ With the application of the principle that the stockholders should bear losses first, it was possible to secure relatively low prices for the acquired assets. This circumvented potential “lemon market” effects. At the same time, there were no incentives established for shareholders to rely on the expectation of government assistance in the future. The partners involved in negotiations for the restructuring of the troubled assets were clearly identifiable and acces-

²⁵ The amount of money still to be invested in order to make the properties of BIH attractive enough for potential buyers is estimated to remain lower than the proceeds from the sale of Landesbank Berlin.

sible, ensuring that assets could be managed actively and effectively. In Sweden and Berlin, the government drew on the expertise of external consultants with distressed asset management experience. The allocation of sufficient funding prevented the premature sale of assets at prices below their future market value. As both the good and bad banks were partially or completely in government hands in each case, no conflict of interest developed between the government and private banks. For this reason, it can be assumed that the management had considerable autonomy over operative decisions.

Proposed Models for the Current Crisis

The gray areas in Table 1 designate proposed models for the current crisis. As the Table shows, the proposals under discussion are often of a “mixed” form. In the USA, the Geithner plan relies on public-private partnerships for the purchase of toxic assets. The original US plan foresaw the creation of a central fund for the acqui-

sition of distressed assets. The latest proposals involve numerous funds with mixed financing. Economists have recently suggested that funds should compete with each other to acquire assets from individual banks and government share capital.²⁶

The German government's bad bank plan proposes a special purpose vehicle (SPV) for each participating bank. The SPV would transfer government bonds at some discount to the participating bank in exchange for the toxic assets (see below for a detailed discussion). The proposal made by the Association of German Banks (BdB), in which an account would be set up for each bank in need of assistance, is aimed at establishing a government-funded bad bank with a mixed organisational structure. It must be noted, however, that mixed solutions are particularly susceptible to conflicts of interest and unclear governance structure.

Efficient Design for a Public Bad Bank

A public bad bank must be in a position to address numerous challenges. First, the transparent removal of troubled assets is necessary in order to ensure that the rescued bank has real prospects for a fresh start. Second, the costs of the bailout for the taxpayer should be minimised. Third, no incentives or new opportunities for opportunistic behaviour in the future should be created. To do this, the implemented bad bank model should limit the potential for "hold-up" problems while emphasising to shareholders and executives that entrepreneurial failure is a real possibility.

The toxic assets currently plaguing the German banking system are for the most part complex mortgage-backed securities originating in the US housing market. The anonymity of the US-based original borrowers and the large number of intermediate institutions involved in the packaging and onward sale of these securities represent serious impediments to the identification of the relevant counterparties for debt restructuring. Hence, there are fewer instruments available for restricting the bad bank's losses than in the past. Basically, the tools are limited to the purchase price, the securing of additional time to sell assets at an opportune moment and the governance structure.

Key Elements of the Bad Bank Design

The selected bad bank plan should consist of the following key elements in order to address the challenges:

- Troubled assets should be valued based on current market prices prior to their takeover by the bad bank. Troubled assets for which there is no market should be

²⁶ L. Bebchuk: Buying Troubled Assets, Discussion Paper No. 636, 4/2009, John M. Olin Center for Law, Economics, and Business, Harvard Law School; L. Bebchuk: Jump-Starting the Market for Troubled Assets, 2009, www.forbes.com/2009/03/03/troubled-assets-relief-opinions-contributors_bad_bank.html.

transferred to the bad bank at a zero price and therefore at zero cost for the government as the bad bank's sponsor.

- The government should recapitalise the rescued bank (the remaining good bank) through the acquisition of a shareholder stake; in extreme cases, the remaining good bank should be taken over by the government.
- The bad bank should be funded by the government. External experts should be entrusted with the management and future sale of the troubled assets at the government's expense. If a profit remains after the proceeds from holding the troubled assets until expiration date and/or selling them to the market have materialised and operating costs have been deducted, these profits should be distributed to the former shareholders.
- The government should announce its commitment to the future re-privatisation of its stake in the rescued bank. When establishing a bad bank, the government should make a binding commitment to how long it has to sell its shares in the good bank following the closure of the bad bank.
- All "systemically relevant" banks should be identified and required to participate in the plan.

The takeover of toxic assets by the government at zero cost and the corresponding write-down of assets will create transparency, avoid the high expense of pricing distressed assets, and will ensure that shareholders are the first ones to bear the cost of failure.²⁷ The risk of moral hazard will also be effectively limited. A zero-cost acquisition is also justified based on the fact that the active management of the troubled assets is impaired by their complex structure. This approach will also keep the bad bank's initial capital requirements at a minimum.

With the value of their toxic assets written down to zero, a number of banks will no longer meet the legislated core capital requirement. The government should take a stake in these banks in order to recapitalise them. The prior removal of troubled assets will limit the risk taken on by the government and provide good prospects for the appreciation of its investment. The government's risk of loss (through the bad bank) and opportunity for success (through the rescued good bank) would thus be clearly separated from one another. This would also contribute to transparency.

The government should bear the costs of running the bad bank and ensure that sufficient capital is available so that assets can be held until their date of maturity or an

²⁷ The European Commission has proposed valuing the troubled assets prior to their transfer on the basis of their inherent value. This would be a very difficult task, however, due to the complexity of the assets. Communication from the Commission, op. cit.

opportune moment for their sale. The risk of exploitation for the party providing the initial capital would be limited by the acquisition of the assets at zero cost. The rule that profits of the bad bank should be returned would ensure that the former shareholders are not forced to suffer any unfair losses from the transfer of the troubled assets to the bad bank.²⁸ In addition, proceeds from the resale of the government's stake in the rescued bank would be used to cover the taxpayer's initial investment for recapitalising the good banks and for possible losses incurred by the bad bank. In this case, the government would have no incentive to delay the resale of the stake it had taken in the rescued bank. Box 1 shows a simple example of how the proposed design would work.

At the very most, the amount of funding that the government will need to provide to recapitalise the banking sector will equal the losses that accrue from the write-down of troubled assets – i.e. somewhere between 200 and 300 billion euros for Germany. The one-off set-up costs and annual operating costs for the bad bank have to be added to this.

German Landesbanken

The proposed design for a bad bank provides the opportunity of solving the long-lasting problem of too many weak Landesbanken in Germany. These publicly owned regional banks are particularly affected by the financial turmoil. The majority of them is extremely debt-ridden and lacks a reliable business model.

Under the plan, a depreciation of the toxic assets' book value according to their zero market value reduces initially the equity of the Landesbanken shareholders – the federal states and the savings banks. A centralised bad bank created by the German government for all ailing Landesbanken takes over the toxic products at a value of zero – and provides for further exploitation at its own expense. Each Landesbank has a separate account at the bad bank. At the same time, the German government recapitalises the remaining good banks, if possible together with the savings banks. In extreme cases, this operation can result in a complete takeover by the consortium of the German government and the savings banks. If the savings banks contribute to the recapitalisation of the good Landesbanken, they receive a pre-emption right for the government's shares. If the savings banks are not available as an investor, the funds for the recapitalisation have to come completely from the government. Deficits of the bad bank shall be borne by the German government; surpluses are transferred to

the current shareholders, i.e. the federal states and the savings banks.

The good banks merge under pressure of their shareholders to one institution. If, after the end of the crisis, the pre-emption right is exercised, the savings banks take over the merger completely. The savings banks may have a strong incentive to become the majority owner. They are in need of a central institution and a clearing agent for their own operations. If the pre-emption right is not exercised, the government can privatise its shares without restrictions to private, cooperative or foreign-based banks.

Currently, at least four of the seven Landesbanken are severely distressed. The German savings banks association already owns almost 100% of the Landesbank Berlin Holding AG, one of the three Landesbanken that are less affected by the crisis. If the savings banks took over the merger, the total number of remaining Landesbanken could be reduced to two. The same number of Landesbanken would evolve if the merger were sold to other banks. In the long run, the remaining two Landesbanken should also be privatised.

The Bad Bank Plan of the German Government

The German government's bad bank programme follows a different agenda than the above proposed design. The two central principles of the proposed design are the provision of a fresh start and the spending of taxpayers' money only for shares of the good banks. Immediate disclosure and write-off of structured products related to sub-prime mortgages is indispensable for this purpose. Systemically relevant banks would be forced to become part of the programme, depreciate and restore their capital basis. Using government money for restoration is compulsory if private funds are not available.

In contrast, in the government's bad bank plan, government bonds are used to compensate the bank for the transfer of the toxic assets to the bad bank. These bonds burden the taxpayers with future debt owned by the participating bank. In addition, the programme allows for the distribution of the losses over time and for a voluntary participation.

If a bank participates it would establish a special purpose vehicle (SPV) – a bad bank – that does not require a banking license. The SPV receives the troubled securities at a 10% discount from the book value. The discount would be reduced if the write-offs cut the core capital ratio to a level below 7%. In return the SPV would transfer a bond in the amount of the discounted book value to the bank. The state, via its bank rescue fund SoFFin, would guarantee the value of the bond at some cost to the bank. On behalf of the state, SoFFin would charge a

²⁸ This idea also forms the basis of the debtor warrant in the Bundesbank's proposed model. If the shareholders have in fact surrendered the assets at a price lower than their market value, they can recover the difference through a debtor warrant.

BAD BANKS

Box 1

Example of How the Proposed Bad Bank Design Works

The following simple example illustrates how the proposed design of a bad bank plan works. Costs for establishing and running the bad bank are neglected for simplicity.

Assume that the bank has total assets of 1000 originally. Toxic assets amount to 100. The rest are liquid assets. The bank has equity capital of value 100 and debt of value 900 (Table 1a). Note that all stocks and flows in the tables represent present values. The toxic assets with zero market price are written off completely (Table 1b). This step results in a complete wipeout of the ailing bank's capital basis (-100). If no private funds were available, the government would invest in shares of the good bank and restore the capital basis in the amount of 90 (Tables 1b and 1c). The fresh equity capital of 90 can be used to grant new business loans. The balance sheet has contracted to the amount of 990.

The bad bank takes in the toxic assets without being subject to future payment obligations (Table 1d). Imagine that the selling price of the toxic assets (or alternatively, the true value of the received total cash flows) turns out to be 50. Then, the final balance sheet of the bad bank (Table 1e) would show a gain of 50 to be distributed to former shareholders. Thus, the total loss of shareholders amounts to 50. Privatisation of the government's shares in the good bank would compensate the taxpayer for providing the funds for recapitalisation to the amount of 90. Note that the assumed toxic assets' true value of 50% is a fairly high number. The ECONOMIST, for example, reported that Merrill Lynch received in July 2008 only 22 cents on the dollar for a portfolio of Collateralized Debt Obligations (CDOs) from hedge fund Lone Star.¹

¹ Thain Takes the Pain, in: The Economist, 31 July 2008. In addition, Merrill Lynch had to finance 75% of the deal by loans to the assets' buyer.

fee for this insurance service. The secure bonds do not qualify as risk-weighted assets, and can be pledged as collateral in exchange for a new credit from the ECB.

Independent experts (e.g. accountants) would determine a so-called fundamental value in a two-step procedure. In the first step, the present value of the assets is derived based on expected future cash flows. From this

value, a premium is deducted,²⁹ presumably to cover for the risk of false valuation. The fundamental value would need confirmation by the banking supervisory authori-

²⁹ Ministry of Finance: Entwurf eines Gesetzes zur Fortentwicklung der Finanzmarktstabilisierung, http://www.bundesfinanzministerium.de/nr_69116/DE/BMF_Startseite/Aktuelles/Aktuelle_Gesetze/Gesetzentwerfe_Arbeitsfassungen/130509_Entw_BadBank.html?__nnn=true (access on 22 May 2009)

ty.³⁰ The bank is indebted to the SPV to the amount of the difference between the transfer value and the fundamental value. This debt is worked off by annuity payments over a period of 20 years maximum. If the bank has not enough cash earnings it can compensate the SPV by shares.

At closure date the bank receives cash as the SPV pays off the government bond. If the SPV would produce a loss in the end³¹, either because the default risk of the structured products turned out higher than originally assumed, or because the assets were sold at a price below the fundamental value, the bank's future earnings would go to the fiscal budget until the deficit is balanced. Possible gains of the SPV would be redistributed to the common equity shareholders. Box 2 shows a simple example that illustrates how the German government's bad bank plan works in principle.

Our proposed design and the government's plan coincide if the fundamental value is set to zero, and if the differential payment would be due immediately. In this case, the bad bank would become a shareholder of the good bank to the extent the bank hands over shares to the SPV. In line with our bad bank design the taxpayers' hold-up risk would then be zero. In contrast, a high fundamental value implies that the mass of the taxpayers' compensation for handing over secure bonds is prolonged for at least 20 years. Future contingencies may render the enforcement of the intended gradual loss realisation by shareholders a difficult task. Because of this enforcement problem, the taxpayers' risk of being held up remains high.

In theory the fundamental value in the government plan does not determine the amount of subsidies that ailing banks receive (see the equal total losses in terms of present values for shareholders in both examples shown in the boxes). However, the supposed zero impact on the taxpayers' total engagement may create an incentive for external experts to value the toxic assets too high.

In contrast to our concept the government's bad bank plan implies a balance sheet extension beyond the original amount. Public recapitalisation of the bank is not intended. Thus, in the absence of private funds for additional equity capital, a participating bank would need to finance new business loans by issuing new debt. Such balance sheet extension reduces the core capital ratio. However, a weakening capital basis creates its own problems for regaining stability in the banking sector. There is the expectation that investors and depositors

want banks to strive for a higher core capital ratio rather than for a lower one. Thus, it remains an open question whether participating banks would indeed increase lending under the government's bad bank plan. In addition, imagine that in the course of building the new financial market architecture, the Basel II framework was adjusted in a way that a bank's leverage affects the capital requirements. Such adjustment would at least partly neutralise the intended unlocking of equity capital, and would create additional pressure to recapitalise banks.

Another problem is that the German government intends to make the bad bank plan optional. Systemically important banks may gamble for resurrection in the sense that they dump the bad bank plan in order to avoid disclosure of losses and simply hope for better times. However, with such behaviour, uncertainty would remain in the market as neither the value of assets nor the amounts of hidden losses of some large banks were disclosed. The comeback of trust into the business models of the banking sector would most likely be undetermined.

Finally, the lack of intention of the central government to become a shareholder in the ailing Landesbanken is a severe obstacle to their consolidation. Mergers can be achieved much more easily if the party with the strong will to arrange the merging also has a strong shareholder position in the merger targets. However, in contrast to our own bad bank plan, the German government's plan fails to provide for an instrument that brings the central government into a strong shareholder position.

Conclusion

Under the terms of the plan, a bad bank and nationalisation are not mutually exclusive alternatives but rather two separate policy options that complement one another. The plan avoids mixed proposals with unclear governance structures and uncertainties about the banks' capacity to raise a sufficient volume of capital. The question as to whether a single bank or multiple bad banks should be established is of secondary importance provided the basic plan selected ensures that: (1) distressed banks are freed of troubled assets and are given a fresh start; (2) the taxpayer is not unnecessarily burdened; and (3) moral hazard and other negative incentives are avoided. Furthermore, in order to provide a foundation for the rescued banks to pursue a sustainable business model, a new regulatory framework for capital markets must be enacted.

Historically, most bank plans have followed a decentralised model (i.e. multiple bad banks). The total assets of the systemically relevant banks currently impacted by the crisis and the oft-cited heterogeneity of the toxic assets plaguing the system also lead to the belief that no

³⁰ Either the Federal Financial Supervisory Authority (BaFin) or the Bundesbank, or both institutions may be in charge.

³¹ The SPV would be liquidated after the asset with the highest maturity has expired, or, alternatively, the last asset has been sold.

BAD BANKS

Box 2

Example of How the German Government's Bad Bank Plan Works

The following analogous example illustrates how the German government bad bank plan works in principle. The original balance sheet of the ailing bank is equivalent. Note that the government again invests the amount of 90 for rescuing the bank. However, in the German government's plan the state uses the funds to compensate the bank for giving up their toxic assets.

The German government plan imposes a discount of 10 from the original book value of the toxic assets (Table 2b). The resulting write-offs cut the equity capital by the same amount. Let's assume that the independent accountants fix the fundamental value at the level of 60. Therefore, in terms of present value, the bank transfers at the expense of its equity the additional discount of 30 to the bad bank over the next 20 years (Tables 2b and Table 2d).

The bad bank takes in the toxic assets for their fundamental value of 60 and hands over insured government bonds of value 90 in exchange (Table 2d). Assume that the bad bank uses zero bonds that expire after 20 years for this purpose. Those bonds can be used as collateral for an ECB loan that is needed to finance the additional discount of 30. The bank's balance sheet contracts to a volume of 990 after the toxic assets are transferred and parts of the equity are swapped for debt (Table 2c).

With an equivalent selling price as in the above example, the final balance sheet of the bad bank (Table 2e) would show a residual deficit of 10, after paying off the expired zero bonds to the bank. With this amount the bank's shareholders would be still indebted to the taxpayers.

Table 2a
Balance Sheet Prior to the Transfer of Toxic Assets

Total loss for shareholders: 50

benefits of scale would be gained by a centralised bad bank solution. To implement the plan and bail out the banking system, the government will need a considerable volume of capital immediately, which is the primary drawback of our proposed plan.

The implementation of a bad bank plan has to go hand in hand with building a new financial market archi-

ture. The boundary problem in the financial sector³² implies that banks may stop supporting a new regulatory framework as soon as bad banks are created and their balance sheet problems are solved.
