fast methods for jackknifing inequality indices

by Lynn Karoly and Carsten Schröder
Fast Methods for Jackknifing Inequality Indices

Lynn Karoly, RAND
Carsten Schröder*, University of Kiel, Department of Economics

Abstract. The jackknife is a resampling method that uses subsets of the original database by leaving out one observation at a time from the sample. The paper outlines a procedure to obtain jackknife estimates for several inequality indices with only a few passes through the data. The number of passes is independent of the number of observations. Hence, the method provides an efficient way to obtain standard errors of the estimators even if sample size is large. We apply our method using micro data on individual incomes for Germany and the US.

Key words: Jackknife; Resampling; Sampling Variability; Inequality

1 Introduction

When examining time-series changes in inequality or cross country differences in inequality, the measured changes are sometimes small. To estimate the precision of a statistic from a sample and to test the statistical significance of changes or cross country differences of the same statistic, the jackknife has been suggested. The jackknife is a resampling method that uses subsets of the original database by leaving out one observation at a time from the sample. So, there are as many subsets as there are observations in the sample, and for each subset the jackknife statistic needs to be computed. This means that the jackknife can become a time intensive procedure when the sample size is large.

Karagiannis and Kovacevic (2000) and Yitzhaki (1991), however, show that jackknifing the Gini coefficient requires only a few passes through the data. We complement these two works on the Gini coefficient by providing efficient jackknife procedures for several frequently applied inequality indices: the coefficient of variation, the variance of the logarithms, the mean log deviation, the Theil index, and the Atkinson index. We show that, after having computed some basic statistics from the overall sample, it takes a single run through the data to derive all the jackknife values of an index from all the subsets. We apply the outlined jackknife procedure to micro data from the Luxembourg Income Study.

Section 2 explains the procedures. Section 3 provides the results from the empirical application. Section 4 concludes. Derivations of all the formulas and STATA codes are provided in an Appendix.

2 Efficient jackknife procedures for inequality indices

The jackknife offers a conceptually simple way to estimate the precision of a statistic (see the pioneering works of Tukey, 1958; Efron, 1982; Efron and Gong, 1983; Wolter, 1985). In the context of inequality measurement, we have a random sample of \( N \) observations on income,
\( y = (y_1, y_2, ..., y_N) \) and sampling weights, \( \omega_1, \omega_2, ..., \omega_N \). Let \( \theta = \theta(y) \) denote our measure of inequality. Let \( \theta_{(i)} = \theta(y_1, y_2, ..., y_{i-1}, y_{i+1}, ..., y_N) \) denote the jackknife estimate of the same measure of inequality for the subset where the \( i \)th observation has been deleted.

Following Wolter (1985), the jackknife estimate of the standard error of \( \theta \) is,

\[
SE_\theta = \left( \frac{N - 1}{N} \sum_{i=1}^{N} \frac{\omega_i}{\bar{\omega}} [\theta_{(i)} - \bar{\theta}]^2 \right)^{0.5},
\]

with \( \bar{\omega} = \frac{1}{N} \sum_{i=1}^{N} \omega_i \).\(^4\) Computing the jackknife standard error estimate relies on the \( N \) values of \( \theta_{(i)} \), one jackknife statistic per subset. For large samples the computational burden to derive equation (1) seems to be large. However, as we will outline below, for standard inequality indices deriving the \( N \) values of \( \theta_{(i)} \) requires just a few passes through the data. Hereby, the number of passes is independent of the number of sample observations, \( N \).

The procedure is detailed below by means of the Theil index, and the variance of logarithms. The general idea of the procedure is to write the jackknife estimates \( \theta_{(1)}, ..., \theta_{(N)} \) as a function of statistics from the overall sample (i.e., as a function of \( \theta \), \( N \), arithmetic or geometric mean) and a subset-specific correction factor that can be derived with a single run through the data. The procedure can be adapted to other inequality indices including indices of the generalized entropy class, and indices based on the variance or social-welfare functions (e.g. the Atkinson index).

We will make use of the following notation and definitions:

1. \( w_i \) denotes the normalized weight, \( w_i = \frac{\omega_i}{\sum_{i=1}^{N} \omega_i} \). Accordingly, \( \sum_{i=1}^{N} w_i = N \).
2. \( \bar{y} \) denotes the arithmetic mean of income, \( \bar{y} = \frac{1}{N} \sum_{i=1}^{N} w_i y_i \).
3. \( y^* \) denotes the geometric mean of income, \( y^* = \exp \left( \frac{1}{N} \sum_{i=1}^{N} w_i \ln(y_i) \right) \). The natural logarithm of the geometric mean is denoted \( \bar{x} = \ln(y^*) = \frac{1}{N} \sum_{i=1}^{N} w_i x_i \) with \( x_i = \ln(y_i) \).

\(^4\) An alternative method is to compute the squared differences between the jackknife statistics and their mean (see, for example, Yitzhaki, 1991).
2.1 Efficient jackknife procedure for the Theil index

The Theil index from the sample is,

\[ \theta_T = \frac{1}{N\bar{y}} \left( \sum_{i=1}^{N} w_i y_i \ln(y_i) \right) - \ln(\bar{y}). \tag{2} \]

The Theil index for the subset where the \( i \)th observation has been deleted is,

\[ \theta_{T(i)} = \frac{1}{(N - w_i)\bar{y}_{(i)}} \left( \sum_{j \neq i} w_j y_j \ln(y_j) \right) - \ln(\bar{y}_{(i)}), \tag{3} \]

with \( \bar{y}_{(i)} \) denoting the arithmetic mean of income from the subset,

\[ \bar{y}_{(i)} = \frac{N\bar{y} - w_i y_i}{N - w_i}. \tag{4} \]

The first step is to write \( \theta_{T(i)} \) in terms of \( \theta_T \). Initially, from (3):

\[ \theta_{T(i)} = \frac{1}{(N - w_i)\bar{y}_{(i)}} \left( \sum_{i=1}^{N} w_i y_i \ln(y_i) \right) - \frac{w_i}{(N - w_i)\bar{y}_{(i)}} y_i \ln(y_i) - \ln(\bar{y}_{(i)}). \tag{5} \]

Rewriting equation (2) gives,

\[ \sum_{i=1}^{N} w_i y_i \ln(y_i) = [\theta_T + \ln(\bar{y})]N\bar{y}, \tag{6} \]

and substituting (6) and (4) into (5) gives,

\[ \theta_{T(i)} = \frac{N\bar{y}}{N\bar{y} - w_i y_i} \left( \theta_T + \ln(\bar{y}) \right) - \frac{w_i y_i \ln(y_i)}{N\bar{y} - w_i y_i} - \ln \left( \frac{N\bar{y} - w_i y_i}{N - w_i} \right). \tag{7} \]

Equation (7) reveals that \( \theta_{T(i)} \) can be expressed as a function of three statistics from the full sample, \( N, \bar{y}, \) and \( \theta_T \), and characteristics of the observation that is left out, \( w_i \) and \( y_i \). Thus, after having calculated \( N, \bar{y}, \) and \( \theta_T \) for the full sample, to compute all the jackknife statistics \( \theta_{T(1)}, \ldots, \theta_{T(N)} \) takes a single pass through the data.
2.2 Efficient jackknife procedure for the variance of logarithms

Applying Bessel’s correction\(^5\), the variance of the logarithms from the sample is,

\[
\theta_{VL} = \frac{1}{N-1} \sum_{i=1}^{N} w_i \ln \left( \frac{y_i}{y^*} \right)^2 = \frac{1}{N-1} \sum_{i=1}^{N} w_i (x_i - \bar{x})^2 \tag{8}
\]

The variance of the logarithms for the subset where the \(i\)th observation has been deleted is,

\[
\theta_{VL(i)} = \frac{1}{N-2} \sum_{j \neq i} w_{j(i)} (x_j - \bar{x}_{(i)})^2, \tag{9}
\]

with \(\bar{x}_{(i)} = \frac{1}{N-w_i} [NW - x_i w_i]\), and with \(w_{j(i)} = \frac{w_j}{(N-w_i)/(N-1)}\) denoting re-weighted normalized weights. By means of the re-weighting the average of \(w_{j(i)}\) over the subset where the \(i\)th observation has been deleted equals unity. So, the analogue of the term \(\frac{1}{N-1}\) in (8) in (9) is \(\frac{1}{N-2}\).

Substituting the definition of \(w_{j(i)}\) in (9) gives:

\[
\theta_{VL(i)} = \frac{(N-1)}{(N-2)(N-w_i)} \sum_{j \neq i} w_j (x_j - \bar{x}_{(i)})^2, \tag{10}
\]

Initially, from (8):

\[
\theta_{VL} = \frac{1}{N-1} \sum_{j \neq i} w_j (x_j - \bar{x})^2 + \frac{1}{N-1} w_i (x_i - \bar{x})^2. \tag{11}
\]

Substituting \(\bar{x} = \frac{1}{N} [(N - w_i)x_{(i)} + x_i w_i]\) in (11) gives:

\[
\theta_{VL} = \frac{1}{N-1} \sum_{j \neq i} w_j \left( x_j - \frac{1}{N} \left( (N - w_i)x_{(i)} + x_i w_i \right) \right)^2 + \frac{1}{N-1} w_i (x_i - \bar{x})^2 \tag{12}
\]

\[
= \frac{1}{N-1} \sum_{j \neq i} w_j \left( x_j - \frac{N}{A} x_{(i)} + \frac{w_i}{N} x_{(i)} - \frac{w_i}{N} x_i \right)^2 + \frac{1}{N-1} w_i (x_i - \bar{x})^2
\]

Equation (12) can be rewritten as:

\(^5\text{Bessel’s correction, the division in the variance formula by } N - 1 \text{ instead of by } N, \text{ secures unbiasoness.}\)
\( \theta_{VL} = \frac{1}{N-1} \sum_{j \neq i}^N w_j (x_j - \bar{x}_i)^2 + \frac{2}{(N-1)} \sum_{j \neq i}^N w_j (x_j - \bar{x}_i) \left(\frac{w_i}{N}(\bar{x}_i - x_i)\right) \\
+ \frac{1}{N-1} \sum_{j \neq i}^N w_j \left(\frac{w_i}{N} \bar{x}_i - \frac{w_i}{N} x_i\right)^2 + \frac{1}{N-1} w_i (x_i - \bar{x})^2 \)

The \( C \)-term on the right handside of (12) can be rewritten as \( = \theta_{VL(i)} \frac{(N-2)(N-w_i)}{(N-1)^2} \). The \( D \)-term is zero since

\( D = \frac{2}{N-1} \sum_{j \neq i}^N w_j (x_j - \bar{x}_i)(\bar{x}_i - x_i) = \frac{2 w_i}{(N-1)N}(\bar{x}_i - x_i) \sum_{j \neq i}^N w_j (x_j - \bar{x}_i) = 0 \)

The \( E \)-term after some algebra becomes,

\( E = \frac{1}{N-1(N-w_i)^2} \sum_{j \neq i} w_j (\bar{x} - x_i)^2 \)

\( = \frac{1}{N-1(N-w_i)^2} (N-w_i)(\bar{x} - x_i)^2 = \frac{1}{N-1(N-w_i)}(\bar{x} - x_i)^2 \)

Substituting (14-15) in (13), the variance of the logarithms for the sample becomes,

\( \theta_{VL} = \theta_{VL(i)} \frac{(N-2)(N-w_i)}{(N-1)^2} + \frac{1}{N-1(N-w_i)}(\bar{x} - x_i)^2 + \frac{w_i}{N-1}(x_i - \bar{x})^2. \)

After some algebra, (16) becomes,

\( \theta_{VL} = \theta_{VL(i)} \frac{(N-2)(N-w_i)}{(N-1)^2} + \frac{Nw_i}{(N-1)(N-w_i)}(\bar{x} - x_i)^2. \)

Solving (17) with respect to \( \theta_{VL(i)} \) gives the desired expression for the jackknife estimator of the variance of the logarithms:

\( \theta_{VL(i)} = \theta_{VL} \frac{(N-1)^2}{(N-2)(N-w_i)} - \frac{Nw_i(N-1)}{(N-w_i)^2(N-2)}(\bar{x} - x_i)^2 \)
Equation (18) is the analogue of the jackknife estimator of the Theil index in equation (7): $\theta_{VL(i)}$ can be expressed as a function of statistics from the full sample $(N, \bar{x},$ and $\theta_{VL})$ and the characteristics of the observation that is left out, $w_i$ and $x_i$. Thus, after having calculated $N, \bar{x},$ and $\theta_{VL}$ for the full sample, computing $\theta_{VL(1)}, \ldots, \theta_{VL(N)}$ takes a single pass through the data.

2.3 Efficient jackknife procedure for other inequality indices

Similar derivations as those explained in Sections 2.1 and 2.2 can be made for other inequality indices. Formulas for an efficient computation of the Atkinson index, $\theta_{A_\varepsilon}$ (with inequality aversion parameter $\varepsilon = 1$ and $\varepsilon = 2$), the mean log deviation, $\theta_{MLD}$, and the coefficient of variation, $\theta_{CV}$, are as follow:

\begin{equation}
\theta_{A_1(i)} = 1 - \frac{\exp \left[ \frac{N}{N-w_i} \ln(y^*) - \frac{\ln(y_i)w_i}{N-w_i} \right]}{Ny_i - w_iy_i}
\end{equation}

\begin{equation}
\theta_{A_2(i)} = 1 - \frac{N-w_i}{Ny_i - w_iy_i} \cdot \frac{N-w_i}{\bar{y}(N-w_i)} \cdot \frac{w_i(Ny_i - w_iy_i)}{y_i(N-w_i)}
\end{equation}

\begin{equation}
\theta_{MLD(i)} = \frac{1}{N-w_i} \left[ \theta_{MLD} - \ln(\bar{y}) \right] + \frac{w_i \ln(y_i)}{N-w_i} + \ln \left( \frac{Ny_i - y_iw_i}{N-w_i} \right)
\end{equation}

\begin{equation}
\theta_{CV(i)} = \frac{\left( \frac{(N-1)^2}{(N-2)(N-w_i)} - \frac{Nw_i(N-1)}{(N-w_i)^2(N-2)} \right) (\bar{y} - y_i)^2}{\left( \frac{1}{(N-w_i)} \right) [Ny_i - y_iw_i]^{0.5}}
\end{equation}

Derivations of the formulas can be found in the Appendix. Again, after having calculated some basic statistics from the full sample, computing all the jackknife indices takes only a single pass through the data.
3 Empirical application

We have calculated the above inequality indices and their associated jackknife confidence intervals for distributions of disposable household incomes in the US and in Germany from the Luxembourg Income Study (LIS) database. For 40 countries and several years, the LIS provides representative micro-level information on private households’ incomes and their demographics.

Our computations rely on the LIS household-level datasets. Household disposable income is our income concept. Household disposable income is harmonized across countries, covers labor earnings, property income, and government transfers in cash minus income and payroll taxes. To adjust household incomes for differences in needs, we have deflated household disposable income by means of the square root equivalence scale. The square root equivalence scale is the number of household members to the power of 0.5. This gives the needs-adjusted equivalent income of the household. Household units are weighted by the frequency weights (as provided in the data) and the number of household members. Our weighting procedure accommodates the principle of normative individualism that considers any person as important as any other. The so derived distribution depicts differences in living standards, captured by differences in equivalent incomes, among individuals (Bönke and Schröder, 2012).

We have removed household observations with missing information or with negative values of disposable income. Moreover, to avoid outlier-driven biases of inequality estimates, we use trimmed data with the one percent observations with the highest and with the lowest incomes being discarded.

It has taken a few seconds to obtain all the results presented in Table 1. The Table is split in two panels. The upper panel provides the results for the US, the lower panel provides the results for Germany. In the US, the results cover the period 1991-2010; in Germany, the results cover the period 1994-2010. For every country-period combination, the Table provides the point estimates of the inequality indices along with their upper and lower bounds of 95 percent confidence intervals, \( CI^\text{lo}_\theta \) and \( CI^\text{hi}_\theta \), derived from the jackknife statistics.

We comment on the US first. An examination of the statistics shows a significant rise of inequality over the observation period: the point estimate of the Theil index increases from 0.161 in 1991 to 0.192 in 2010, and the confidence intervals are clearly distinct: \([0.158;0.165]\) vs.
[0.189; 0.196]. However, some inter-temporal changes in inequality for this sample are not statistically significant (e.g. 1997-2000; 2000-2004; 2004-2007).

For Germany, we also see a significant rise of inequality over the observation period. This is due to a prominent rise of inequality between 2000 and 2004. The inter-temporal comparisons before the rise (1994-2000) and after the rise (2004-2007 and 2007-2010) indicate no significant changes in inequality.

Comparing inequality levels in the US and Germany there is significantly more inequality in the US. The result holds for all six inequality indices and all the observed points in time.⁶

**4 Conclusion**

This paper has outlined a procedure to obtain jackknife estimates for several inequality indices with only a few passes through the data. The number of passes is independent of the number of observations: After having computed some statistics from the overall sample, computing all the jackknife indices takes only a single pass through the data. Hence, the method provides an efficient way to get standard errors of the estimators even if sample size is large.

We have applied our method using data from the Luxembourg Income Study to evaluate the statistical significance of inter-temporal inequality in Germany and the US, and also to evaluate cross country differences in inequality levels.

⁶ We have executed our empirical analysis using the alternative formulation of the standard error introduced in footnote 4. It did not change our conclusions since confidence intervals changed very little.
References

Appendix

A.1 Derivation of jackknife formulas

Mean log deviation (Entropy 0)

\( (1_{MLD}^{MLD}) \quad \theta_{MLD} = \frac{1}{N} \sum_{i=1}^{N} w_i \ln \left( \frac{\bar{y}}{y_i} \right) = -\frac{1}{N} \sum_{i=1}^{N} w_i \ln(y_i) + \ln(\bar{y}) \)

\( (2_{MLD}^{MLD}) \quad \theta_{MLD(i)} = -\frac{1}{N-w_i} \sum_{j \neq i} w_j \ln(y_j) + \ln(\bar{y}) \)

From \( (2_{MLD}^{MLD}) \):

\( (3_{MLD}^{MLD}) \quad \theta_{MLD(i)} = -\frac{1}{N-w_i} \left[ \sum_{j \neq i} w_j \ln(y_j) + w_i \ln(y_i) \right] + \frac{w_i \ln(y_i)}{N-w_i} + \ln(\bar{y(i)}) \)

\( (4_{MLD}^{MLD}) \quad \theta_{MLD(i)} = -\frac{1}{N-w_i} \left[ \sum_{i=1}^{N} w_i \ln(y_j) \right] + \frac{w_i \ln(y_i)}{N-w_i} + \ln(\bar{y(i)}) \)

Substituting \(-N[\theta_{MLD} - \ln(\bar{y})] = \sum_{i=1}^{N} w_i \ln(y_i)\) from \((1_{MLD}^{MLD})\) gives:

\( (5_{MLD}^{MLD}) \quad \theta_{MLD(i)} = -\frac{1}{N-w_i} \left[ -N[\theta_{MLD} - \ln(\bar{y})] \right] + \frac{w_i \ln(y_i)}{(N-w_i)} + \ln(\bar{y(i)}) \)

Substituting \(\bar{y(i)}\) by \(\frac{N\bar{y} - y_i w_i}{N-w_i}\) gives:

\( (6_{MLD}^{MLD}) \quad \theta_{MLD(i)} = \frac{1}{N-w_i} \left[ \theta_{MLD} - \ln(\bar{y}) \right] + \frac{w_i \ln(y_i)}{N-w_i} + \ln \left( \frac{N\bar{y} - y_i w_i}{N-w_i} \right) \)
Atkinson Index

The general form of the Atkinson index is, \( \theta_{A_\varepsilon} = 1 - \left[ \frac{1}{N} \sum_{i=1}^{N} w_i \left( \frac{\bar{y}}{y_i} \right)^{1-\varepsilon} \right]^{\frac{1}{1-\varepsilon}} \). Below we derive the jackknife formulas for two prominent cases of the inequality aversion parameter, \( \varepsilon \).

**Inequality aversion parameter \( \varepsilon = 1 \)**

\[
(1^A_1) \quad \theta_{A_1} = 1 - \frac{y^*}{\bar{y}} = 1 - \frac{\exp \left[ \frac{1}{N} \sum_{i=1}^{N} w_i \ln(y_i) \right]}{\bar{y}}
\]

\[
(2^A_1) \quad \theta_{A_1(i)} = 1 - \frac{\exp \left[ \frac{1}{N-w_i} \sum_{j \neq i} w_j \ln(y_j) \right]}{\bar{y}(i)}
\]

Expansion of the term in brackets in the numerator with \( \frac{\ln(y_i)w_i}{N-w_i} - \frac{\ln(y_i)w_i}{N-w_i} \), and substitution of \( \bar{y}(i) \) by \( \frac{N\bar{y}-y_iw_i}{N-w_i} \) gives:

\[
(3^A_1) \quad \theta_{A_1(i)} = 1 - \frac{\exp \left[ \frac{N}{N-w_i} \left( \frac{1}{N} \sum_{i=1}^{N} w_i \ln(y_i) \right) - \frac{\ln(y_i)w_i}{N-w_i} \right]}{\frac{N\bar{y}-y_iw_i}{N-w_i}}
\]

Substitution of the term \( \frac{1}{N} \sum_{i=1}^{N} w_i \ln(y_i) \) (log of the geometric mean of income from the full sample) by \( \ln(y^*) \) gives:

\[
(4^A_1) \quad \theta_{A_1(i)} = 1 - \frac{\exp \left[ \frac{N}{N-w_i} \ln(y^*) - \frac{\ln(y_i)w_i}{N-w_i} \right]}{\frac{N\bar{y}-y_iw_i}{N-w_i}}
\]

**Inequality aversion parameter \( \varepsilon = 2 \)**

\[
(1^A_2) \quad \theta_{A_2} = 1 - \frac{N}{\sum_{i=1}^{N} w_i \frac{\bar{y}}{y_i}}
\]

\[
(2^A_2) \quad \theta_{A_2(i)} = 1 - \frac{N-w_i}{\sum_{j \neq i}^{N} w_j \frac{\bar{y}(i)}{y_j}}
\]
Expansion of the denominator with \( w_i \frac{\bar{y}(i)}{\bar{y}} \bar{y}_{i} - w_i \frac{\bar{y}(i)}{y} y_{i} \), and rewriting the sum gives:

\[
(3^A_2) \quad \theta_{A_2(i)} = 1 - \frac{N - w_i}{\left( \frac{\bar{y}(i)}{\bar{y}} \sum_{j \neq i} w_j \frac{\bar{y}}{y_j} \right) + w_i \frac{\bar{y}(i)}{y} y_{i} - w_i \frac{\bar{y}(i)}{y} y_{i}}
\]

\[
(4^A_2) \quad \theta_{A_2(i)} = 1 - \frac{N - w_i}{\left( \frac{\bar{y}(i)}{\bar{y}} \sum_{i=1}^{N} w_i \frac{\bar{y}}{y_i} \right) - w_i \frac{\bar{y}(i)}{y} y_{i}}
\]

From \( \theta_{A_2} = 1 - \frac{N}{\sum_{i=1}^{N} w_i \frac{\bar{y}}{y_i}} \) it follows that \( \sum_{i=1}^{N} \frac{w_i \bar{y}}{y_i} = \frac{N}{1 - \theta_{A_2}} \), and replacement of the sum in the denominator gives:

\[
(5^A_2) \quad \theta_{A_2(i)} = 1 - \frac{N}{\bar{y}(i)} \frac{N}{1 - \theta_{A_2}} \left( \frac{w_i \bar{y}(i)}{y_i} \right)
\]

Finally, substitution of \( \bar{y}(i) \) by \( \frac{N \bar{y} - w_i \bar{y}_i}{N - w_i} \) gives:

\[
(6^A_2) \quad \theta_{A_2(i)} = 1 - \frac{N - w_i}{\frac{N \bar{y} - w_i \bar{y}_i}{\bar{y}(N - w_i)} \frac{N}{1 - \theta_{A_2}} - \frac{w_i (N \bar{y} - w_i \bar{y}_i)}{y_i(N - w_i)}}
\]
Variance and Coefficient of Variation

\( (1^V) \quad \theta_\nu = \frac{1}{N - 1} \sum_{i=1}^{N} w_i (y_i - \bar{y})^2 \)

\( (2^V) \quad \theta_{\nu(i)} = \frac{(N - 1)}{(N - 2)(N - w_i)} \sum_{j \neq i} w_j (y_j - \bar{y}(i))^2 \)

Rewriting of \( \theta_\nu \) gives:

\( (3^V) \quad \theta_\nu = \frac{1}{N - 1} \sum_{j \neq i} w_j (y_j - \bar{y}(i))^2 + \frac{1}{N - 1} w_i [y_i - \bar{y}]^2 \)

Substituting \( \bar{y} = \frac{1}{N} [(N - w_i)\bar{y}(i) + y_i w_i] \) and reorganizing in analogy to the variance of the logarithms gives:

\( (4^V) \quad \theta_\nu = C + D + E + \frac{1}{N - 1} w_i (y_i - \bar{y})^2 \)

\( (5^V) \quad C = \frac{1}{N - 1} \sum_{j \neq i} w_j (y_j - \bar{y}(i))^2 = \theta_{\nu(i)} \frac{(N - 2)(N - w_i)}{(N - 1)^2} \)

\( (6^V) \quad D = \frac{2}{N - 1} \frac{w_i}{N} \sum_{j \neq i} w_j (y_j - \bar{y}(i)) (\bar{y}(i) - y_i) \)

\[ = \frac{2 w_i}{(N - 1)^2} \left( \bar{y}(i) - y_i \right) \sum_{j \neq i} w_j (y_j - \bar{y}(i)) = 0 \]

\( (7^V) \quad E = \frac{1}{N - 1} \left( \frac{w_i}{N} \right)^2 \sum_{j \neq i} w_j (\bar{y}(i) - y_i)^2 \)

Analogously to \( \theta_{\nu L} \) we can rewrite (7\(^V\)) as:

\( (8^V) \quad E = \frac{1}{N - 1} \frac{w_i^2}{N - w_i} (\bar{y} - y_i)^2 \)

Substituting (5\(^V\)), (6\(^V\)), and (8\(^V\)) in (4\(^V\)) gives:
\[ (9^v) \quad \theta_v = \theta_{v(i)} \frac{(N-2)(N-w_i)}{(N-1)^2} + \frac{1}{N-1} \frac{w_i}{N-w_i} (\bar{y} - y_i)^2 + \frac{w_i}{N-1} (y_i - \bar{y})^2 \]

Analogously to \( \theta_{vl} \), we can rewrite \( (9^v) \) as:

\[ (9^v) \quad \theta_v = \theta_{v(i)} \frac{(N-2)(N-w_i)}{(N-1)^2} + \frac{nw_i}{(N-1)(N-w_i)} (\bar{y} - y_i)^2 \]

Solving \( (9^v) \) for \( \theta_{v(i)} \) gives:

\[ (10^v) \quad \theta_{v(i)} = \theta_v \left( \frac{(N-1)^2}{(N-2)(N-w_i)} - \frac{nw_i(N-1)}{(N-w_i)^2(N-2)} (\bar{y} - y_i)^2 \right) \]

The coefficient of variation is defined as,

\[ (1^{CV}) \quad \theta_{cv} = \frac{(\theta_v)^{0.5}}{\bar{y}} \]

Hence,

\[ (2^{CV}) \quad \theta_{cv(i)} = \frac{(\theta_{v(i)})^{0.5}}{\bar{y}(i)} \]

Substitution of \( \theta_{v(i)} = \theta_v \left( \frac{(N-1)^2}{(N-2)(N-w_i)} - \frac{nw_i(N-1)}{(N-w_i)^2(N-2)} (\bar{y} - y_i)^2 \right) \) and of \( \bar{y}(i) = \frac{1}{(N-w_i)} [(N\bar{y} - y_iw_i)] \) in \( (2^{CV}) \) gives,

\[ (3^{CV}) \quad \theta_{cv(i)} = \frac{\left( \theta_v \left( \frac{(N-1)^2}{(N-2)(N-w_i)} - \frac{nw_i(N-1)}{(N-w_i)^2(N-2)} (\bar{y} - y_i)^2 \right)^{0.5} \right)}{\frac{1}{(N-w_i)} [(N\bar{y} - y_iw_i)]} \]
